

SYSTEM 4/50 - 70 ALGOL

REPORT 2.

THE INTERMEDIATE CODE

4th May 1966.

L.W.Moore

INTRODUCTION

The design of the Intermediate Code generated by Phase 1Ø of the S4/50 Algol Compiler is based on that of the Object Program produced by the Whetstone KDF9 Algol Translator (as defined in 'Algol 60 Implementation' by B. Randell and L.J. Russell, Academic Press, 1964). There are however differences consequent upon (i) the three-pass structure of the S4/50 Algol Compiler, which is designed to generate machine code as the end product, and (ii) the altered method of handling the run-time stack, now based on the ideas of the ALCOR-ILLINOIS 7090 Compiler.

This document has a scope restricted to a definition of those parts of the S4/50 Algol Intermediate Code which differ from the corresponding parts of the Whetstone KDF9 Algol Object Program. It is a reference document only.

Further documents will deal with detailed aspects of the various Phases of the Compiler and of the generated object program.

1, LABELS

Mnemonic labels appearing in the Position Identifier Table have the following significance:-

Gg --- internally generated labels
 Ll --- user's own labels
 Pp --- procedure labels

These labels are entered in the P.I.T. when and only when they occur as declarations (left-hand labels).

Throughout this document these labels, in both their left - and right-hand incarnations, have been written explicitly into the intermediate code for clarity of exposition.

In fact, left-hand labels have no existence in the intermediate code. They exist only as entries in the P.I.T.

Right-hand labels in the intermediate code are pointers to the appropriate entry in the P.I.T., and occupy two bytes. Denoting this two-byte pointer by p the label operations, with their parameters, are:-

TL (k,p),n (Take label)
 UJ (p)
 etc. (Unconditional Jump)

Parameters such as (k,p) - written in the examples explicitly as e.g. (k,G5) - denote that k, p are packed into 2 bytes with 4 bits for k, 12 bits for p. This implies a maximum limit of 4096 labels in any module.

1 A) Note on Use of Labels and Switches

The translation of a designational expression into intermediate code will not explicitly involve use of the operations GTA, GTFA. Instead, the following convention is used:-

a) Within an actual parameter expression or a switch declaration:

The label operations TL, TFLN, TFLV, SINDR, and TFS have the run-time effect of stacking the resulting label

FFSk	
N	Address

b) Elsewhere:

i) The operation TL does not stack its label at run-time, but uses registers to effect an immediate transfer of control, using an implied GTA.

ii) The operations TFLN, TFLV, SINDR, and TFS, at run-time, all operate on the previously-stacked label, effecting an immediate transfer of control using an implied GTFA.

The operations GTA, GTFA therefore do not appear in the intermediate code.

This convention leads to some simplification of the intermediate code, as illustrated in the following example.

Example :-

'IF' A 'THEN' L1 'ELSE' S [2]
 (A boolean, L1 label, S switch)

a) Within actual parameter
 expression, or switch

BEX

TBR (k,s)

IFJ (G1)

TL (k,L1),n

UJ (G2)

G1: SAPP

TIC (2)

SINDR (k,S)

G2:

b) Elsewhere

BEX

TBR (k,s)

IFJ (G1)

TL (k,L1),n

G1: SAPP

TIC (2)

SINDR (k,S)

Case (a) is the normal Whetstone form of the translation, case (b) is the abbreviated form made possible by the convention described above.

2. BLOCKS

Within a hierarchy, block structure is represented in the Intermediate Code (I/C) by:-

BE (n) (BE \equiv Block Entry)

BEND (n) (BEND \equiv Block End)

n = block nesting number for the current hierarchy, starting from one at the start of the procedure body. For a labelled procedure body, n for the label is zero.

BE The action of BE at run time is to plant the current value of WP (working pointer) into word n of the Block Index List.

BEND The run-time action of BEND is to replace WP by the contents of word (n-1) of the Block Index List.

3B) Calls of Function Designators, and Procedure Statements

The call operations for the various kinds of procedure are:-

CF	- Call function	CFZ (k, π)	- Call function zero
CTF	- Call type function	CTFZ (k, π)	- Call type function zero
CFF (k,s)	- Call formal function	CFFZ (k,s), π	- Call formal function zero
CTFF (k,s)	- Call type formal function	CTFFZ (k,s), π	Call type formal function zero.

The operations CF, CTF require no parameters, since they are always preceded by an APP operation whose parameter (π) gives the necessary information. In the case of calls of procedures which have no parameters (CFZ, etc) this information (π) has to appear as a parameter to the call operation itself. π is a pointer to the π th entry in level parameter table (a), which contains among other things a pointer to the entry for the procedure in the Position Identifier Table.

A function call which invokes a procedure as a function designator uses one of the operations

CTF, CTFZ(k, π), CTF(k,s), CTFZ(k,s), π .

The corresponding call invoking a procedure as a procedure statement uses one of the operations

CF, CFZ(k, π), CFF(k,s), CFFZ(k,s), π .

Use of a CF type operation (procedure statement) will imply a following REJECT operation. The effect of this implied REJECT is to delete the unused or superfluous result accumulator on exit from the called procedure

3C) Parameter List Operations

The only operations necessary are:-

CRFA	-	Copy real formal array)	
CIFA	-	Copy integer formal array)	Arrays by value
CBFA	-	Copy boolean formal array)	
CA	-	Check array	-	All arrays by name
CP	-	Check parameter	-	All other quantities by name or by value

3D) Actual Operations

At a procedure call the generated actual operations are:-

PSR (Gg)	Parameter subroutine		
PRA (k,s),-	Par. real array		
PIA (k,s),-	Par. integer array		
PBA (k,s),-	Par. boolean array		
PSW (k,p),-	Par. switch	PFSW (k,s),-	Par. formal switch
PPR π ,-,-	Par. procedure	PFPR (k,s), π	Par. formal procedure
PIF π ,-,-	Par. integer function	PFFI (k,s), π	Par. formal fn.integer
PRF π ,-,-	Par. real function	PFFR (k,s), π	Par. formal fn.real
PBF π ,-,-	Par. boolean function	PFFB (k,s), π	Par. formal fn.boolean
PST (<string>)	Par. string	PFST (k,s),-	Par. formal string
PIC (const)	Par. integer constant		
PRC (const)	Par. real constant		
PBC (const)	Par. boolean constant		
PI (k,s),-	Par. integer	PFIR (k,s),-	Par. formal integer
PR (k,s),-	Par. real	PFRR (k,s),-	Par. formal real
PB (k,s),-	Par. boolean	PFBR (k,s),-	Par. formal boolean
PL (k,p),n	Par. label	PFLN (k,s),-	Par. formal label (name)
		PFLV (k,s),-	Par. formal label (value)

'-' indicates a 1 byte space.

The label parameter to PSR is the label of the next actual operation or of the CF - type operation, whichever is appropriate. The subroutine heralded by PSR is always terminated by an EIS (End Implicit Subroutine) operation. PSR is used for any actual parameter whose evaluation requires more than one intermediate code operation (expressions, array elements, designational expressions). The body of an implicit subroutine contains ordinary I/C operations. (TRA, TFAB, CFFZ etc).

Actual Operations - General Structure of Procedure Call

	APP (k, π)		'Actual parameters' marker π = procedure no. (0-15 if formal procedure) APP <u>absent</u> if no parameters.
	PSR (G1)	}	Implicit subroutine
	EIS		
G1:	PRF π ,--		
	PBF π ,--		
	PSR (G2)	}	Implicit subroutine
	EIS		
G2:			
	PFIR (k,s),-		
G3:	CF		Procedure call

Actual Operations - Example of a Procedure Call

P (A, 4, 'TRUE', X + Y, C, 'IF' I = 0 'THEN' R1 'ELSE' R2;
 S, Q, <PING>, F, B [1,4], T [2]);

The following types are assumed for the variables occurring in these actual parameters:-

A	real	
X	real	
Y	real	formal
C	real array	
I	integer	
R1	label	
R2	label	
S	switch	
Q	integer procedure	
F	procedure	formal
B	integer array	
T	switch	

	APP (k, π)		actual parameters marker
	PER (k,s),-		A
	PIC (4)		4
	PBO (<u>true</u>)		<u>true</u>
	PSR (G1))	
	TRR (k,s))	
	TFR (k,s))	X + Y
	+)	
	EIS)	
G1:	PRA (k,s),-		C
	PSR (G2))	
	SEX)	
	TIR (k,s))	
	TIC \emptyset)	R1 or R2
	=)	
	IFJ (G3))	
	TL (k,R1), n)	
	UJ (G4))

G4:	EIS)	
G2:	PSW (k,p),-		S
	PIF π ,--		Q
	PST (<PING>)		<PING>
	PIPR (k,s), π		F
	PSR (G5))	
	TIAA (k,s))	
	TIC1)	
	TIC (4))	B [1,4]
	INDR)	
	EIS)	

G5: PSR (G6))
SAPP)
TIC (2)) T [2]
SINDR (k,T))
EIS)

G6: CF Call procedure P

3E) Use of Formal Parametersa) By Value

The straightforward operations TIR, TRA, etc are used, the address parameters to which point to the appropriate formal accumulator. This is because parameters by value are regarded as local variables to the procedure.

b) By Name

TFAR (k,s))	Addresses of arithmetic formal variables
TFAI (k,s))	
TFR (k,s))	Values of arithmetic formal variables
TFI (k,s))	
TFAB (k,s)		Address of formal boolean
TFB (k,s)		Value of formal boolean
TFS (k,s)		Formal switch
CFP (k,s)		Formal procedure
CFPZ (k,s), π		Formal procedure zero
CTFP (k,s)		Type formal procedure
CTFPZ (k,s), π		Type formal procedure zero

c) Labels

TFLM (k,s)	By name .
TFLV (k,s)	By value

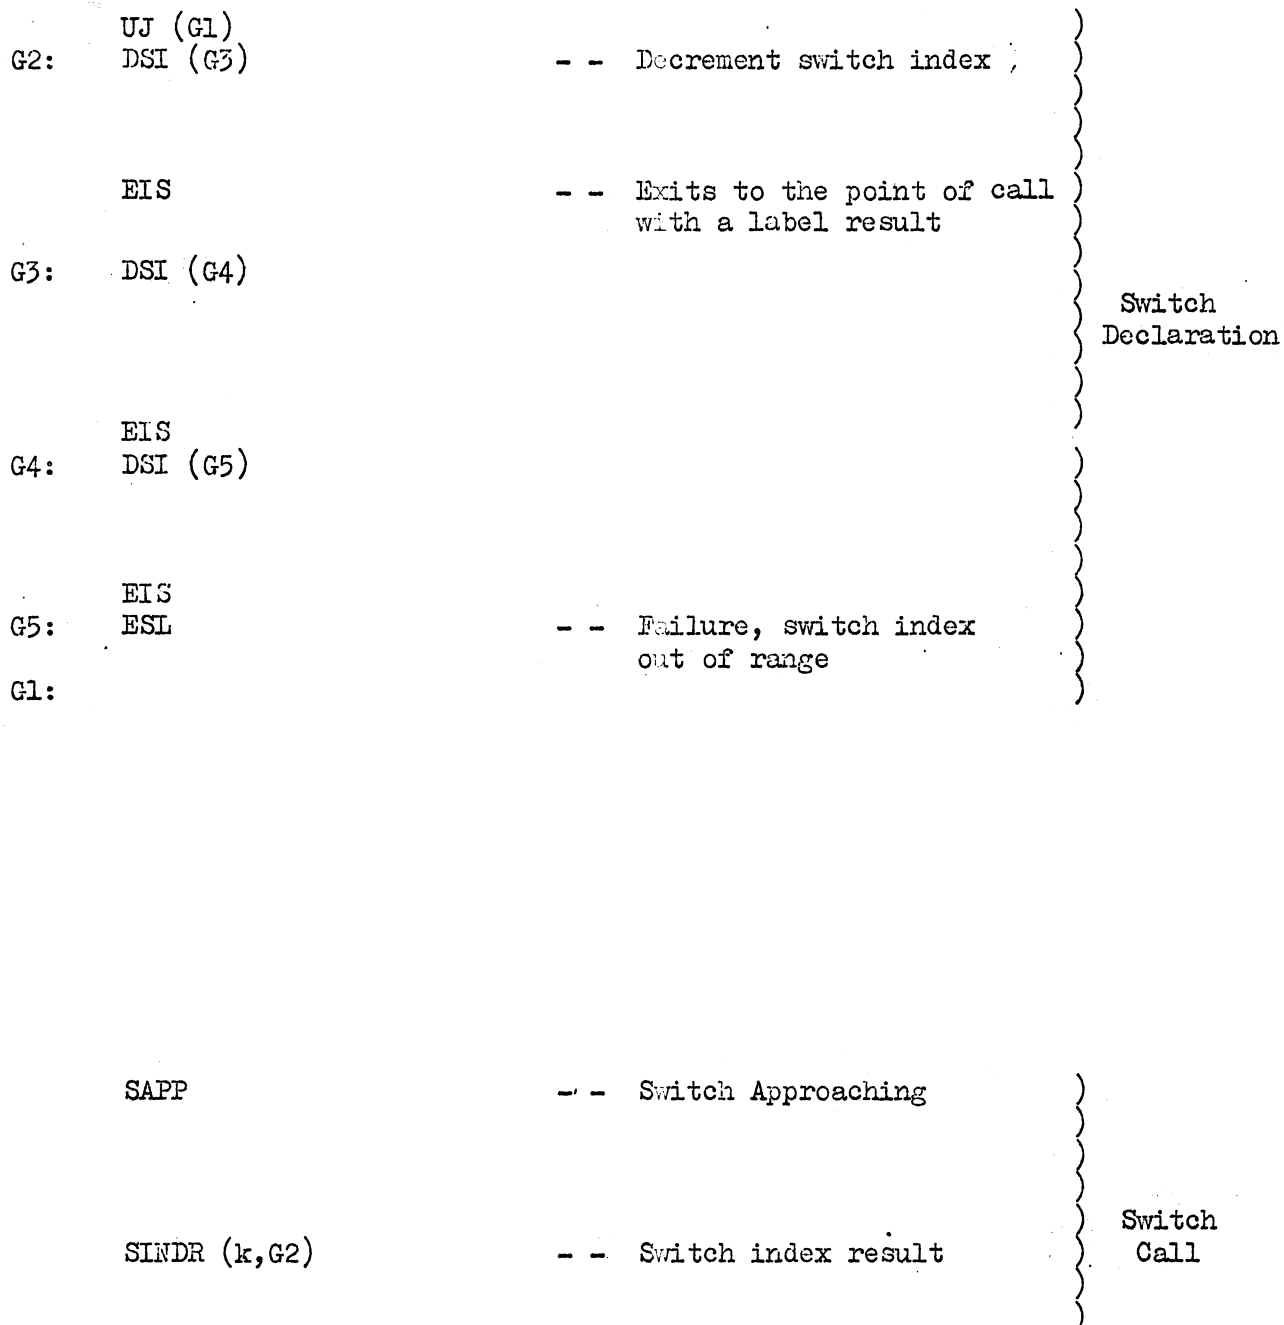

d) Arrays

Arrays used as formal parameters (by name or by value) require no special operations, since the array parameter is the array word.

4. SWITCHES

4A) This implementation depends on the fact that the complement of the switch index is handed over, from the call to the declaration of the switch, in a register.

The overall structure of a switch is as follows:-

N.B. The first DSI operation at a switch declaration must be labelled.

4B) Switch elements and Array elements as Actual Parameters

If an actual parameter in a procedure call is written as e.g.

S [2]

it may not be known whether S is a switch or an array until later in the translation. It is therefore necessary to allow space for either interpretation in the I/C.

The alternative final translations are:-

<u>switch element</u>		<u>array element</u>
SAPP)	
DUMMY) corresponds to	TRA (k,s)
DUMMY)	
SINDR (k,G2)	corresponds to	(INDR
		(DUMMY
		(DUMMY
TFS (k,s)	corresponds to	(INDR
		(DUMMY
		(DUMMY

6. FOR STATEMENTS6A) General:

A for statement is converted into a normal block, which opens with the I/C operation

$$FBE (n)$$

and closes with

$$BEND (n)$$

The first order working storage of the for block is given by

$$L_{\text{for}} = 10 + \text{first order working storage required by the controlled statement.}$$

The value 10 arises from the need for six parameters which control the running of the various for list elements. These parameters are:-

address (k,n) :	FI	(integer)	:	the for index
" (k,n+1) :	TI	(integer)	:	the text index
				(initially TI = FI)
" (k,n+2) :	S1)	various parameters needed for the implementation of step until elements (g.v.)
" (k,n+4) :	S2)	
" (k,n+6) :	S3)	
" (k,n+8) :	S4	(integer))	
" (k,n+9) :	spare		:	for alignment

The two I/C operations DFI (Gg) (Decrement For Index) and AST (Gg) (Avoid Step) are introduced, the expansions for which in I/C would be:

DFI (Gg)	{	TIA (k,n+1)	AST(Gg)	{	TIR (k,n + 3)
	{	TIR (k,n+1)		{	TICØ
	{	TICI		{	=
	{	-		{	IFJ (Gg)
	{	STA			
	{	TICØ			
	{	=			
	{	IFJ (Gg)			

6B) Structure of for statement with 3 elements

```

EEND (n)
TI: = S4: = ∅

G1: AC: = address of controlled variable v      - - - - (TS = Top of Stack)
      S3: = value of controlled variable v

      FI: = FI + 1
      TI: = TI
      DFI (G3)      - - - - Decrement TI and jump if ≠ ∅
                    }
                    }
                    }
      ST
      UJ (G2)      - - - - jump to controlled statement

G3: DFI (G4)
                    }
                    }
                    }
      ST
      UJ (G2)

G4: DFI (G5)
                    }
                    }
                    }
      ST

G2:
                    }
                    }
                    }
      UJ (G1)      - - - - Return to G1 for next
                    element, or to continue
                    current element.

G5: EEND (n)

```

6R) Example of a for statement

```
'FOR' A := 1 'STEP' 2 'UNTIL' 10, 1, A + 2 'WHILE' A 'LT' 10
      'DO' I := A;
```

This statement is assumed to occur in block 3 of hierarchy 2, and the stack addresses are assumed to be:-

A	(2,14)	(real)
I	(2,17)	(integer)
TI	(2,18)	(integer)
TI	(2,19)	(integer)
S1	(2,20)	(integer)
S2	(2,22)	(integer)
S3	(2,24)	(real)
S4	(2,26)	(integer)

The translation is:-

	FEE (4)	
	TIA (2,18)	
	TIA (2,26)	
	TIC \emptyset	
	STA	
	ST	FI: = S4: = \emptyset
G1:	TRA (2,14)	TS: = address of controlled variable A
	TRA (2,24)

CONTROLLED STATEMENT:

G7: TIA (2,17)
 TRR (2,14)
 ST
 UJ (G1)

I : = A
 Return for next element

G9: BEND (4)

7. Own Variables

Identified as hierarchy -1 (i.e. k for an own variable is 4 bits of all ones).

Own variables at run time reside at the end of the program's (or module's) constant space. Space for all own variables used in a program is reserved immediately on entry to the program.

8. ARRAYS

Where
uses the operat

$MRSF(k, \dots, a$
 $MISF(k, s), \dots, s), a$
 $MBSF(k, s), a$ $MOBSF(k, s) a$

for real, integer, and boolean arrays respectively, where (k, s) is the stack address of the appropriate array word.

IMDA, INDR remain unchanged, and are parameterless.

Further, to assist the optimisation of accessing elements of 1 dimensional arrays, the operations

TRAA (k, s)	Take real array address
TIAA (k, s)	Take integer array address
TBAA (k, s)	Take boolean array address

are introduced. These take the place of the operations TRA, TIA, TBA for obtaining the address of the array word.

9. NOTE ON SEGMENTS AND MODULES

The standard function

```
FETCH (<IDENT>);
```

will bring the segment <IDENT> into the store using the Control Routine FETCH. It will not enter any of the segment's constituent modules.

The specification of a module (i.e. an independently compiled procedure) within the calling program will be e.g.

```
'PROCEDURE' P(A); 'REAL' A;
'ENTER' <IDENT> , <LANGUAGE>;
```

where <IDENT> is the identifier of the module to be entered, and <LANGUAGE> specifies the language in which the module was written.

The call of this module will be written in the usual way, as P(X);

The fetch operation for a segment must have been performed in the program dynamically before any call of a constituent module of the segment, unless it is already in store by virtue of having been linked with a prior segment or program.

Any module not written in Algol (or 4/50 assembly code) has linked with it an environment module.

The action of the routine ENTER is to enter the environment module for the body concerned, if this body is in a language other than Algol, and to hand across the address (provided by "linkage editor") of the body being called. The environment module arranges the information available (stack, etc.) in the form required by the body, plants a return address into a place recognised by the body, and transfers control to the body.

After the body has been obeyed its normal return mechanism will transfer control back to the environment module, which then resets the information available into the form required by the Algol base program, and finally performs an ordinary procedure return to the point of call of the body by working on the links in the Algol stack.

10. DICTIONARY OF INTERMEDIATE CODE OPERATIONS

Operation		Parameters
AOA	Avoid Own Array	p
APP	Actual Parameters	k, π
AST	Avoid Step	p
BE	Block Entry	n
BEND	Block End	n
BEX	Boolean Expression	-
CA	Check Array	-
CBFA	Copy Boolean Formal Array	-
CF	Call Function	-
CFE	Call Formal Function	(k, s)
CFEZ	Call Formal Function Zero	(k, s), π
CFZ	Call Function Zero	k, π
CIFA	Copy Integer Formal Array	-
CP	Check Parameter	-
CREA	Copy Real Formal Array	-
CTF	Call Type Function	-
CTFE	Call Type Function Formal	(k, s)
CTFEZ	Call Type Function Formal Zero	(k, s), π
CTFZ	Call Type Function Zero	k, π
DEI	Decrement For Index	p
DSI	Decrement Switch Index	p
DUMMY	Dummy	-

Operation		Parameters
EIS	End Implicit Subroutine	-
ESL	End Switch List	-
FBE	For Block Entry	n
FINISH	Finish	-
IFJ	If False Jump	p
INDA	Index Address	-
INDR	Index Result	-
MBSF	Make Boolean Storage Function	(k,s),a
MISF	Make Integer Storage Function	(k,s),a
MOBSF	Make Own Boolean Storage Function	(k,s),a
MOISF	Make Own Integer Storage Function	(k,s),a
MORSF	Make Own Real Storage Function	(k,s),a
MRSF	Make Real Storage Function	(k,s),a
NEG	Negate	-
PB	Parameter Boolean	(k,s),-
PBA	Parameter Boolean Array	(k,s),-
PBC	Parameter Boolean Constant	constant
PBF	Parameter Boolean Function	$\pi, -, -$
PE	Procedure Entry	(k,L),m,N
PFBR	Parameter Formal Boolean Result	(k,s),-
PFTB	Parameter Formal Function Boolean	(k,s), π
PFFI	Parameter Formal Function Integer	(k,s), π
PFFR	Parameter Formal Function Real	(k,s), π

Operation		Parameters
PPIR	Parameter Formal Integer Result	(k,s),-
PFLN	Parameter Formal Label (Name)	(k,s),-
PFLV	Parameter Formal Label (Value)	(k,s),-
PFRR	Parameter Formal Real Result	(k,s),-
PFST	Parameter Formal String	(k,s),-
PFSW	Parameter Formal Switch	(k,s),-
PFPR	Parameter Formal Procedure	(k,s), π
PI	Parameter Integer	(k,s),-
PIA	Parameter Integer Array	(k,s),-
PIC	Parameter Integer Constant	constant
PIF	Parameter Integer Function	$\pi,-,-$
PL	Parameter Label	(k,p),n
PPR	Parameter Procedure	$\pi,-,-$
PR	Parameter Real	(k,s),-
PRA	Parameter Real Array	(k,s),-
PRC	Parameter Real Constant	constant
PRF	Parameter Real Function	$\pi,-,-$
PSR	Parameter Subroutine	p
PST	Parameter String	'string'
PSW	Parameter Switch	(k,p),-
RETURN	Return	-
SAPP	Switch Approaching	-
SINDR	Switch Index Result	(k,p)

Operation		Parameters
ST	Store	-
STA	Store Also	-
TBA	Take Boolean Address	(k,s)
TBAA	Take Boolean Array Address	(k,s)
TBCF	Take Boolean Constant False	-
TBCT	Take Boolean Constant True	-
TBR	Take Boolean Result	(k,s)
TFAB	Take Formal Address Boolean	(k,s)
TFAI	Take Formal Address Integer	(k,s)
TFAR	Take Formal Address Real	(k,s)
TFB	Take Formal Boolean	(k,s)
TFI	Take Formal Integer	(k,s)
TFIN	Take Formal Label (Name)	(k,s)
TFLV	Take Formal Label (Value)	(k,s)
TFR	Take Formal Real	(k,s)
TFS	Take Formal Switch	(k,s)
TIA	Take Integer Address	(k,s)
TIAA	Take Integer Array Address	(k,s)
TIC	Take Integer Constant	constant
TICØ	Take Integer Constant Zero	-
TIC1	Take Integer Constant One	-
TIR	Take Integer Result	(k,s)
TL	Take Label	(k,p),n

Operation	Description	Parameters
TRA	Take Real Address	(k,s)
TRAA	Take Real Array Address	(k,s)
TRC	Take Real Constant	constant
TRR	Take Real Result	(k,s)
UJ	Unconditional Jump	p
+		
-		
*		
/		
'/'		
'**'		
'GT'		
'GE'

'NE'		
'LE'		
'LT'		
'NOT'		
'AND'		
'OR'		
'IMPL'		
'EQUIV'		
FAIL	Compilation Failure	r

PARAMETER NOTATION

p	p'th entry in Position Identifier Table ($1 \leq p$) (2 bytes)
(k,p)	k and p packed into 2 bytes with 4 bits for k and 12 bits for p, where k is the hierarchy number and p is the packed form of the p defined above ($0 \leq k$)
(k,s)	k and s packed into 2 bytes with 4 bits for k and 12 bits for s, where s is the number of words up the stack from the start of the link data for hierarchy k. (Stack Address).
(k,L)	k and L packed into 2 bytes with 4 bits for k and 12 bits for L, where L is the number of words of first order working storage (including parameter space and link data) for the hierarchy and its constituent blocks.
n	n'th block level in current (or destination) hierarchy. (1 byte) ($1 \leq n$)
π	π 'th entry in list (a) of the Level Parameters (1 byte) ($1 \leq \pi$)
m	Number of words of parameter space (1 byte)
N	Total block nesting depth within current hierarchy. (1 byte) ($1 \leq N$)
constant	1 word for integer or boolean constants, 2 words for real constants.
'string'	Basic symbol representation (unpacked) of the string, including the opening and closing string quotes.
- (minus sign)	One-byte space
a	Number of arrays in an array segment (1 byte).
r	r'th failure for this module (1 byte). ($1 \leq r$)

A new operation FAIL has been added whose decimal representation is 248

12. The Intermediate Code Operation FAIL

Any syntactic failure detected by Phase 10 results in

- a) a failure message to a listing device, and
- b) the compilation of the intermediate code operation

FAIL (r)

where the current failure is the r'th to be detected.

The translation then continues (including the generation of intermediate code).

Phase 20 translates this operation into an entry into the run-time failure routine. The result is that at run-time the first of these entries to the failure routine to be dynamically encountered causes the listing of a failure message and the termination of the run. The failure message will include the identifier of the module in which the failure occurred.

The justification of this process is that the user in many cases will be able to obtain satisfactory results from his run before the error condition is encountered.

S4-50/70 ALGOL

REPORT 2, THE INTERMEDIATE CODE

AMENDMENT I. 17th JUNE 1966.

page 3.4

The parameters to the four operations PPR, PIF, PRF, and PBF have been changed to:-

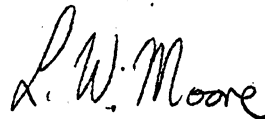

PPR k, π , -

PIF k, π , -

PRF k, π , -

PBF k, π , -

These operations are also used on pages 3.5, 3.7, 10.2, 10.3.

L.W. Moore.
