ALGOL 60

Modified report on the algorithmic language ALGOL 60
Preface to this edition

This document constitutes the definition of the programming language ALGOL 60, as established by the International Federation for Information Processing, in an authoritative version. It is a corrected reprint of the Modified Report on the Algorithmic Language ALGOL 60, as published in the Computer Journal, Vol. 19, p. 364–376.

The purpose of this edition is
1. To make the definition of ALGOL 60 better available to the interested public. It has already been published in a learned journal, with the condition that reproduction of the report, for any purpose, but only of the whole text, is explicitly permitted without formality.
2. To provide a document with authoritative status, while ensuring the highest accuracy possible, by establishing a definitive text, in the interest of both users and implementors of ALGOL 60.
3. To provide a document suitable for reference within an International Standard, in accordance with ISO Directives, Annex 3C.

Any revisions of this document, though none are envisaged, will be properly announced at least a year before publication.

DELFt, September 1981

Critical note on the text:

The text of the Modified Report on the Algorithmic Language ALGOL 60, as presented, has been taken from The Computer Journal, Vol. 19, p. 364–379, with two corrections: one in 4.6.4.2, documented as an Erratum in The Computer Journal, Vol 20, p. 232, the other in Appendix 2 (outreal), an obvious omission, submitted by Dr. I.D. Hill, IFIP/TC 2/WG 2.1 ALGOL 60 Maintenance Group.
Modified Report on the Algorithmic Language

ALGOL 60

being the

Revised Report on the Algorithmic Language ALGOL 60
(dedicated to the memory of William Turanski)

as modified by

R. M. De Morgan, I. D. Hill and B. A. Wichmann

under the authority of IFIP Working Group 2.1.

If any man, who shall desire a more particular account of the several Alterations . . . shall take the pains to compare the present Book with the former; we doubt not but the reason of the change may easily appear. Preface to Book of Common Prayer 1662.

Introduction

For the history of ALGOL 60 up to April 1962, the Revised Report on ALGOL 60 (Naur, 1963) should be consulted.

Following the publication of the Revised Report, responsibility for ALGOL was transferred to Working Group 2.1 of IFIP Technical Committee 2. In 1964 WG2.1 produced reports on a subset of the language (IFIP, 1964a), and on input/output procedures (IFIP, 1964b), but thereafter devoted most of its attention to a proposed new language that was eventually adopted as ALGOL 68—a separate development, with which the present Report is not concerned.

Additional proposals for a different subset and for input/output were proposed by the European Computer Manufacturers' Association (ECMA) (1965) and by the Association for Computing Machinery (ACM) (Knuth et al, 1964) respectively.

In 1972 a version of the Revised Report, together with the various proposals on subsets and input/output, was published by the International Organization for Standardization as ISO Recommendation 1338 (1972), but IFIP refused to recognise this document as valid. Three subsets were given as Level 1 (ECMA, with recursion), Level 2 (ECMA) and Level 3 (IFIP), the full language being called Level 0.

Meanwhile, various defects have been noted in the language definition which have unnecessarily hindered the use of ALGOL. Although the existence of subsets has given some assistance to the compiler-writer and user of the language, numerous problems exist, some of which were noted in the Revised Report.

Hence the need for a detailed commentary and standard interpretation has become apparent. Such a commentary is now available, some of which were noted in the Revised Report. A preliminary version was discussed at the 1974 meeting of Working Group 2.1 at Breukelen. A revised version appeared in ALGOL Bulletin No. 38, together with a questionnaire and a request for comments. A further revision was based on the replies, and discussed at the 1975 meeting of Working Group 2.1 at Munich, where it was recommended for publication as an IFIP document.

Description of the reference language

1. Structure of the language

The algorithmic language has two different kinds of representation—reference and hardware—and the development described in the sequel is in terms of the reference representation. This means that all objects defined within the language are represented by a given set of symbols—and it is only in the choice of symbols that other representations may differ. Structure and content must be the same for all representations.

Reference language

1. It is the defining language.
2. The characters are determined by ease of mutual understanding and not by any computer limitations, coder's notation, or pure mathematical notation.
3. It is the basic reference and guide for compiler builders.
4. It is the guide for all hardware representations.

Hardware representations

Each one of these:
1. is a condensation of the reference language enforced by the limited number of characters on standard input equipment;
2. uses the character set of a particular computer and is the language accepted by a translator for that computer;
3. must be accompanied by a special set of rules for transliterating to or from reference language.

It should be particularly noted that throughout the reference language underlying in typescript or manuscript, or boldface type in printed copy, is used to represent certain basic symbols (see Sections 2.2.2 and 2.3). These are understood to have no relation to the individual letters of which they are composed. In the reference language underlying or boldface is used for no other purpose.

The purpose of the algorithmic language is to describe computational processes. The basic concept used for the description of calculating rules is the well-known arithmetic expression containing as constituents numbers, variables, and functions. From such expressions are compounded, by applying rules of arithmetic composition, self-contained units of the language—explicit formulae—called assignment statements.

To show the flow of computational processes, certain non-arithmetic statements and statement clauses are added which may describe, e.g. alternatives, or iterative repetitions of computing statements. Since it is sometimes necessary for the function of these statements that one statement refers to another, statements may be provided with labels. A sequence of statements may be enclosed between the statement brackets begin and end to form a compound statement.

Statements are supported by declarations which are not themselves computing instructions, but inform the translator of the existence and certain properties of objects appearing in statements, such as the class of numbers taken on as values by a variable, the dimension of an array of numbers, or even the set of rules defining a function. A sequence of declarations followed by a sequence of statements and enclosed between begin and end constitutes a block. Every declaration appears in a block in this way and is valid only for that block.

A program is a block or a compound statement that is contained only within a fictitious block (always assumed to be present and called the environmental block), and that makes no use of statements or declarations not contained within itself, except that it may invoke such procedure identifiers and function designators as may be assumed to be declared in the environmental block.

The environmental block contains procedure declarations of standard functions, input and output operations, and possibly other
operations to be made without declaration, and initialisation, of own variables (see Section 5).

In the sequel the syntax and semantics of the language will be given.

Whenever the precision of arithmetic is stated as being in general not specified, or the outcome of a certain process is left undefined or said to be undefined, this is to be interpreted in the sense that a program only defines a computational process if the accompanying information specifies the precision assumed, the kind of arithmetic assumed, and the course of action to be taken in all such cases as may occur during the execution of the computation.

1. Formalism for syntactic description

The syntax will be described with the aid of metalinguistic formulae (Backus, 1959). Their interpretation is best explained by an example:

\[ <ab> ::= (|) | <ab><d> \]

Sequences of characters enclosed in the brackets \( \langle \rangle \) represent metalinguistic variables whose values are sequences of symbols. The marks \( ::= \) and \( | \) (the latter with the meaning of ‘or’) are metalinguistic connectives. Any mark in a formula, which is not a variable or a connective, denotes itself (or the class of marks which are similar to it). Juxtaposition of marks and/or variables in a formula signifies juxtaposition of the sequences denoted. Thus the formula above gives a recursive rule for the formation of values of the variable \( <ab> \). It indicates that \( <ab> \) may have the value \( ( \text{or} \) or \( ( \text{or} \) and given some legitimate value of \( <ab> \), another may be formed by following it with the character \( ( \text{or} \) by following it with some value of the variable \( <d> \). If the values of \( <d> \) are the decimal digits, some values of \( <ab> \) are:

\[
[(137) \quad (12345) \quad (123456) \quad (123456789) \quad (1234567890)]
\]

In order to facilitate the study, the symbols used for distinguishing the metalinguistic variables (i.e. the sequences of characters appearing within the brackets \( \langle \rangle \)) as \( ab \) in the above example) have been chosen to be words describing approximately the nature of the corresponding variable. Where words which have appeared in this manner are used elsewhere in the text they will refer to the corresponding syntactic definition. In addition some formulae have been given in more than one place.

**Definition:**

\( <\text{empty}> ::= \)

(i.e. the null string of symbols).

2. Basic symbols, identifiers, numbers, and strings. Basic concepts

The reference language is built up from the following basic symbols:

\[
<\text{basic symbol}> ::= <\text{letter}> <\text{digit}> <\text{logical value}> <\text{delimiter}>
\]

2.1. Letters

\[
<\text{letter}> ::= a | b | c | d | e | f | g | h | i | j | k | l | m | n | o | p | q | r | s | t | u | v | w | x | y | z
\]

This alphabet may arbitrarily be restricted, or extended with any other distinctive character (i.e. character not coinciding with any digit, logical value or delimiter).

Letters do not have individual meaning. They are used for forming identifiers and strings (see Sections 2.4 Identifiers, 2.6 Strings). Within this report the letters (from an extended alphabet) \( \Gamma, \Theta, \Sigma \) and \( \Omega \) are sometimes used and are understood as not being available to the programmer. If an extended alphabet is in use, that does include any of these letters, then their uses within this report must be systematically changed to other letters that the extended alphabet does not include.

2.2. Digits and logical values

2.2.1. Digits

\[
<\text{digit}> ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
\]

Digits are used for forming numbers, identifiers, and strings.

2.2.2. Logical values

\[
<\text{logical value}> ::= \text{true} | \text{false}
\]

The logical values have a fixed obvious meaning.

2.3. Delimiters

\[
<\text{delimiter}> ::= <\text{operator}> <\text{separator}> <\text{bracket}> <\text{declarator}> \]

\[
<\text{operator}> ::= <\text{arithmetic operator}> <\text{relational operator}> <\text{logical operator}> <\text{sequential operator}>
\]

\[
<\text{arithmetic operator}> ::= + | - | \times | \div | \%
\]

\[
<\text{relational operator}> ::= = | = | = | = | < | = | = | < | > | > | < | > | =
\]

\[
<\text{logical operator}> ::= \& | \& | \lor | \lor | \lnot | \lnot
\]

\[
<\text{sequential operator}> ::= \text{go to} | \text{if} | \text{then} | \text{else} | \text{for} | \text{do}
\]

\[
<\text{declarator}> ::= \text{begin} | \text{end} | \text{step} | \text{until} | \text{while} | \text{comment}
\]

\[
<\text{specifier}> ::= \text{string} | \text{variable} | \text{value}
\]

Delimiters have a fixed meaning which for the most part is obvious or else will be given at the appropriate place in the sequel.

Typographical features such as blank space or change to a new line have no significance in the reference language. They may, however, be used freely for facilitating reading.

For the purpose of including text among the symbols of a program the following ‘comment’ conventions hold:

\[
<\text{begin comment}> <\text{any sequence of zero or more characters not containing } > ; ; <\text{begin}> <\text{end}> <\text{any sequence of zero or more basic symbols not containing } end \text{ or else or } > ; ; <\text{end}>
\]

By equivalence is here meant that any of the three structures shown in the left hand column may be replaced, in any occurrence outside of strings, by the symbol shown on the same line in the right hand column without any effect on the action of the program. It is further understood that the comment structure encountered first in the text when reading from left to right has precedence in being replaced over later structures contained in the sequence.

2.4. Identifiers

2.4.1. Syntax

\[
<\text{identifier}> ::= <\text{letter}> <\text{identifier}> <\text{letter}> <\text{identifier}> <\text{digit}>
\]

2.4.2. Examples

\[
q \quad \quad \text{Soup} \quad \quad \text{V17a} \quad \quad a3kTMNs \quad \quad \text{MARILYN}
\]

2.4.3. Semantics

Identifiers have no inherent meaning, but serve for the identification of simple variables, arrays, labels, switches, and procedures. They may be chosen freely. Identifiers also act as formal parameters of procedures, in which capacity they may represent any of the above entities, or a string.

The same identifier cannot be used to denote two different quantities except when these quantities have disjoint scopes as defined by the declarations of the program (see Section 2.7 Quantities, kinds and scopes and Section 5 Declarations). This rule applies also to the formal parameters of procedures, whether representing a quantity or a string.

2.5. Numbers

2.5.1. Syntax

\[
<\text{unsigned integer}> ::= <\text{digit}> <\text{unsigned integer}> <\text{digit}>
\]

\[
<\text{integer}> ::= <\text{unsigned integer}> + <\text{unsigned integer}>
\]

\[
<\text{decimal fraction}> ::= <\text{unsigned integer}> <\text{exponent part}>
\]

\[
<\text{decimal operator}> ::= = 10 <\text{integer}>
\]

\[
<\text{decimal number}> ::= <\text{unsigned integer}> <\text{decimal fraction}>
\]

\[
<\text{number}> ::= <\text{decimal number}> <\text{exponent part}>
\]

\[
<\text{number}> ::= <\text{unsigned number}> + <\text{unsigned number}>
\]

\[
<\text{unsigned number}> ::= <\text{decimal number}> <\text{exponent part}>
\]

\[
<\text{exponent part}> ::= <\text{unsigned integer}>
\]

\[
<\text{decimal fraction}> ::= <\text{unsigned integer}>
\]

\[
<\text{decimal operator}> ::= <\text{unsigned integer}>
\]

\[
<\text{decimal number}> ::= <\text{unsigned integer}> <\text{decimal fraction}>
\]

\[
<\text{number}> ::= <\text{decimal number}> <\text{exponent part}>
\]

The logical values have a fixed obvious meaning.
2.5.2. Examples

2.5.3. Semantics

Decimal numbers have their conventional meaning. The exponent part is a scale factor expressed as an integral power of 10.

2.5.4. Types

Integers are of integer type. All other numbers are of real type (see Section 5.1 Type declarations).

2.6. Strings

2.6.1. Syntax

2.6.2. Examples

2.6.3. Semantics

In order to enable the language to handle sequences of characters the string quotes ' and " are introduced.

The characters available within a string are a question of hardware representation, and further rules are not given in the reference language. However, it is recommended that visible characters, other than ' or " should represent themselves, while invisible characters other than space should not occur within a string. To conform with Draft ISO/TR 1672, a space may stand for itself, although in this document the character _ is used to represent a space.

To allow invisible, or other exceptional characters to be used, they are represented within either matching string quotes or a matched pair of the ' symbol. The rules within such an inner string are unspecified, so if such an escape mechanism is used a comment is necessary to explain the meaning of the escape sequence.

A string of the form <proper string><closed string><open string> behaves as if it were the string formed by deleting the closing string quote of the closed string and the opening string quote of the following string (together with any layout characters between them).

Strings are used as actual parameters of procedures (see Sections 3.2 Function designators and 4.7 Procedure statements).

2.7. Quantities, kinds and scopes

The following kinds of quantities are distinguished: simple variables, arrays, labels, switches, and procedures.

The scope of a quantity is the set of statements and expressions in which the declaration of the identifier associated with that quantity is valid. For labels see Section 4.1.3.

2.8. Values and types

A value is an ordered set of numbers (special case: a single number), an ordered set of logical values (special case: a single logical value), or a label.

Certain of the syntactic units are said to possess values. These values will in general change during the execution of the program. The values of expressions and their constituents are defined in Section 3. The value of an array identifier is the ordered set of values of the corresponding array of subscripted variables (see Section 3.1.4.1).

The various types (integer, real, Boolean) basically denote properties of values. The types associated with syntactic units refer to the values of these units.

3. Expressions

In the language the primary constituents of the programs describing algorithmic processes are arithmetic, Boolean, and designational expressions. Constituents of these expressions, except for certain delimiters, are logical values, numbers, variables, function designators, labels, switch designators, and elementary arithmetic, relational, logical, and sequential operators. Since the syntactic definition of both variables and function designators contains expressions, the definition of expressions, and their constituents, is necessarily recursive.

\[
\langle \text{expression} \rangle ::= \langle \text{arithmetic expression} \rangle | \langle \text{Boolean expression} \rangle | \langle \text{designational expression} \rangle
\]

3.1. Variables

3.1.1. Syntax

\[
\langle \text{variable identifier} \rangle ::= \langle \text{identifier} \rangle
\]

\[
\langle \text{simple variable} \rangle ::= \langle \text{variable identifier} \rangle
\]

\[
\langle \text{expression} \rangle ::= \langle \text{arithmetic expression} \rangle
\]

\[
\langle \text{script list} \rangle ::= \langle \text{expression} \rangle | \langle \text{script list} \rangle ,
\]

\[
\langle \text{variable} \rangle ::= \langle \text{simple variable} \rangle | \langle \text{subscripted variable} \rangle
\]

3.1.2. Examples

\[
\langle \text{variable} \rangle ::= \text{epsilon} \quad \text{detA} \quad \text{at17} \\
\langle \text{subscripted variable} \rangle ::= \langle \text{array identifier} \rangle [ \langle \text{script list} \rangle ] \\
\langle \text{variable} \rangle ::= \langle \text{simple variable} \rangle | \langle \text{subscripted variable} \rangle
\]

3.1.3. Semantics

A variable is a designation given to a single value. This value may be used in expressions for forming other values and may be changed at will by means of assignment statements (see Section 4.2). The type of the value of a particular variable is defined in the declaration for the variable itself (see Section 5.1 Type declarations) or for the corresponding array identifier (see Section 5.2 Array declarations).

3.1.4. Subscripts

3.1.4.1. Subscripted variables designate values which are components of multidimensional arrays (see Section 5.2 Array declarations). Each arithmetic expression of the subscript list occupies one subscript position of the subscripted variable and is called a subscript. The complete list of subscripts is enclosed in the subscript brackets { }. The array component referred to by a subscripted variable is specified by the actual numerical value of its subscripts (see Section 3.3 Arithmetic expressions).

3.1.4.2. Each subscript position acts like a variable of integer type and the evaluation of the subscript is understood to be equivalent to an assignment to this fictitious variable (see Section 4.2.4). The value of the subscripted variable is defined only if the value of the subscript expression is within the subscript bounds of the array (see Section 5.2 Array declarations).

3.1.5. Initial values of variables

The value of a variable, not declared own, is undefined from entry into the block in which it is declared until an assignment is made to it. The value of a variable declared own is zero (if arithmetic) or false (if Boolean) on first entry to the block in which it is declared. On subsequent entries it has the same value as at the preceding exit from the block.

3.2. Function designators

3.2.1. Syntax

\[
\langle \text{procedure identifier} \rangle ::= \langle \text{identifier} \rangle \\
\langle \text{actual parameter} \rangle ::= \langle \text{string} \rangle | \langle \text{expression} \rangle \\
\langle \text{array identifier} \rangle | \langle \text{switch identifier} \rangle \\
\langle \text{procedure identifier} \rangle \\
\langle \text{letter string} \rangle ::= \langle \text{letter} \rangle | \langle \text{letter string} \rangle \langle \text{letter} \rangle \\
\langle \text{parameter delimiter} \rangle ::= \langle \text{letter string} \rangle \\
\langle \text{actual parameter list} \rangle ::= \langle \text{actual parameter} \rangle | \langle \text{parameter delimiter} \rangle \langle \text{actual parameter} \rangle \\
\langle \text{actual parameter part} \rangle ::= \langle \text{empty} \rangle | \langle \text{actual parameter list} \rangle \\
\langle \text{function designator} \rangle ::= \langle \text{procedure identifier} \rangle \\
\langle \text{actual parameter part} \rangle
\]
3.2. Examples

\[ \sin(a - b) \]
\[ J(v + s, n) \]
\[ R \]
\[ S(t - 5) \]
\[ \text{Temperature}(T) \]
\[ \text{Pressure}(P) \]
\[ \text{Compile}(':=\ ') \]
\[ \text{Stack}(:Q) \]

3.2.3. Semantics

Function designators define single numerical or logical values which result through the application of given sets of rules defined by a procedure declaration (see Section 5.4 Procedure declarations) to fixed sets of actual parameters. The rules governing specification of actual parameters are given in Section 4.7 Procedure statements. Not every procedure declaration defines rules for determining the value of a function designator.

3.2.4. Standard functions and procedures

Certain standard functions and procedures are declared in the environmental block with the following procedure identifiers:

- abs, labs, sign, enter, sqrt, sin, cos, arctan, ln, exp, inchar, outchar, length, outstring, outterminator, stop, fault, integer, outinteger, unreal, outreal, maxreal, minreal, maxint and epsilon.

For details of these functions and procedures, see the specification of the environmental block given as Appendix 2.

3.3. Arithmetic expressions

3.3.1. Syntax

\[ \langle \text{adding operator} \rangle ::= \text{+} | \text{-} \]
\[ \langle \text{multiplying operator} \rangle ::= \times | \div \]
\[ \langle \text{primary} \rangle ::= (\text{signed number}) | \langle \text{variable} \rangle \]
\[ \langle \text{function designator} \rangle | \langle \text{arithmetic expression} \rangle \]
\[ \langle \text{factor} \rangle ::= \langle \text{primary} \rangle \langle \text{factor} \rangle \]
\[ \langle \text{term} \rangle ::= \langle \text{factor} \rangle \langle \text{term} \rangle \langle \text{multiplying operator} \rangle \langle \text{factor} \rangle \]
\[ \langle \text{simple arithmetic expression} \rangle ::= \langle \text{term} \rangle \langle \text{simple arithmetic expression} \rangle \langle \text{adding operator} \rangle \langle \text{term} \rangle \]
\[ \langle \text{if clause} \rangle ::= (\text{if Boolean expression} \rangle \langle \text{simple arithmetic expression} \rangle \text{else} \langle \text{simple arithmetic expression} \rangle \]
\[ \langle \text{arithmetic expression} \rangle ::= \langle \text{term} \rangle \]

3.3.2. Examples

Primaries:

- \[ 7.39410 - 8 \]
- \[ \text{sum} w[i \div 2, 8] \]
- \[ \cos (y + z \times 3) \]
- \[ (a - 3) / (y + w_i[t][8]) \]

Factors:

- \[ \text{omega} \]
- \[ \text{sum} \times \text{cos}(y + z \times 3) \]
- \[ 7.39410 - 8 \times \text{w}[i \div 2, 8, 8] \times (a - 3) / (y + w_i[t][8]) \]

Terms:

- \[ U \]
- \[ \text{omega} \times \text{sum} \times \text{cos}(y + z \times 3) / 7.39410 - 8 \]
- \[ \text{w}[i \div 2, 8, 8, 8] / (a - 3) / (y + w_i[t][8]) \]

Simple arithmetic expression:

- \[ U - \text{Y} + \text{omega} \times \text{sum} \times \text{cos}(y + z \times 3) / 7.39410 - 8 \]
- \[ \text{w}[i \div 2, 8, 8, 8] / (a - 3) / (y + w_i[t][8]) \]

Arithmetic expressions:

- \[ w \times u - Q(S + Ca) / 2 \]
- \[ \text{if} q > 0 \text{ then } S + V \times Q / (A \text{ else } 2) \times S + 3 \times q \]
- \[ \text{if} a = 0 \text{ then } U / V \text{ else if } a > 17 \text{ then } U / V \text{ else if } k \neq y \text{ then } V / U \text{ else } 0 \]
- \[ a \times \sin(\text{omega} \times r) \]
- \[ 0.5 \times \text{abs}(a(N \times (N - 1) / 2, 0)) \times (A \times \text{arctan}(y) + Z) / (7 + Q) \]
- \[ \text{if} q \text{ then } n - 1 \text{ else } n \]
- \[ \text{if} a < 0 \text{ then } A / B \text{ else if } b = 0 \text{ then } B / A \text{ else } z \]

3.3.3. Semantics

An arithmetic expression is a rule for computing a numerical value.

In the case of simple arithmetic expressions this value is obtained by executing the indicated arithmetic operations on the actual numerical values of the primaries of the expression, as explained in detail in Section 3.3.4 below. The actual numerical value of a primary is obvious in the case of numbers. For variables it is the current value (assigned last in the dynamic sense), and for function designators it is the value arising from the computing rules defining the procedure (see Section 5.4.4 Values of function designators) when applied to the current values of the procedure parameters given in the expression. Finally, for arithmetic expressions enclosed in parentheses the value must through a recursive analysis be expressed in terms of the values of primaries of the other three kinds.

In the more general arithmetic expressions, which include if clauses, one out of several simple arithmetic expressions is selected on the basis of the actual values of the Boolean expressions (see Section 3.4 Boolean expressions). This selection is made as follows: The Boolean expressions of the if clauses are evaluated one by one in sequence from left to right until one having the value true is found. The value of the arithmetic expression is then the value of the first arithmetic expression following this Boolean (the longest arithmetic expression found in this position is understood). If none of the Boolean expressions has the value true, then the value of the arithmetic expression is the value of the expression following the final else.

The order of evaluation of primaries within an expression is not defined. If different orders of evaluation would produce different results, due to the action of side effects of function designators, then the program is undefined.

In evaluating an arithmetic expression, it is understood that all the primaries within that expression are evaluated, except those within any arithmetic expression that is governed by an if clause but not selected by it. In the special case where an exit is made from a function designator by means of a go to statement (see Section 5.4.4), the evaluation of the expression is abandoned, when the go to statement is executed.

3.3.4. Operators and types

Apart from the Boolean expressions of if clauses, the constituents of simple arithmetic expressions must be of real or integer types (see Section 5.1 Type declarations). The meaning of the basic operators and the types of the expressions to which they lead are given by the following rules:

3.3.4.1. The operators +, −, and × have the conventional meaning (addition, subtraction, and multiplication). The type of the expression will be integer if both of the operands are of integer type, otherwise real.

3.3.4.2. The operations \( \langle \text{term} \rangle / \langle \text{factor} \rangle \) and \( \langle \text{term} \rangle \div \langle \text{factor} \rangle \) both denote division. The operations are undefined if the factor has the value zero, but are otherwise to be understood as a multiplication of the term by the reciprocal of the factor with due regard to the rules of precedence (see Section 3.3.5). Thus for example

\[ a / b \times 7 / (p - q) = a / v / s \]

means

\[ (((a \times (b - 1)) \times 7) \times ((p - q) - 1)) \times v \times (s - 1) \]

The operator / is defined for all four combinations of real and integer types and will yield results of real type in any case. The operator \( \div \) is defined only for two operands both of integer type and will yield a result of integer type. If a and b are of integer type, then the value of \( a \div b \) is given by the function:

\[ \text{integer procedure div}(a, b); \]

\[ \text{value a, b}; \]

\[ \text{integer a, b}; \]

\[ \text{if b = 0 then } \]

\[ \text{fault('div-by-zero', a)} \]

\[ \text{else} \]

\[ \text{begin integer q, r}; \]

\[ q := 0; r := \text{abs}(a); \]

\[ \text{for r := r - \text{abs}(b) while r \geq 0 do q := q + 1; } \]

\[ \text{div := if a < 0, b > 0 then } -q \text{ else q } \]

\[ \text{end div} \]

3.3.4.3. The operation \( \langle \text{factor} \rangle ^{\langle \text{primary} \rangle} \) denotes exponentiation, where the factor is the base and the primary is the exponent. Thus
for example, \(2^n \uparrow k\) means \((2^n)^k\).

while

\[
2^n \uparrow m = \sum_{k=0}^{m} \binom{m}{k} 2^{n \cdot k}
\]

If \(r\) is of real type and \(x\) of either real or integer type, then the value of \(x \uparrow r\) is given by the function:

\[
\text{real procedure} \ \text{expr}(x, r); \ \text{value} \ x, r;
\]

\[
\text{real} \ x, r;
\]

\[
\text{if} \ x > 0.0 \ \text{then} \ \text{expr} := \text{expr}(r \times \ln(x));
\]

\[
\text{else} \ \text{if} \ x = 0.0 \ \land \ r > 0.0 \ \text{then}
\]

\[
\text{expr} := 0.0
\]

\[
\text{else}
\]

\[
\text{fault}(\text{expr}_{\uparrow\text{undefined}}, x)
\]

If \(i\) and \(j\) are both of integer type, then the value of \(i^j\) is given by the function:

\[
\text{integer procedure} \ \text{exp}(i, j); \ \text{value} \ i, j;
\]

\[
i, j;
\]

\[
\text{if} \ j < 0 \ \lor \ i = 0 \ \land \ j = 0 \ \text{then}
\]

\[
\text{fault}(\text{exp}_{\uparrow\text{undefined}}, j)
\]

\[
\text{else}
\]

\[
\begin{align*}
\text{begin} \\
\text{integer} \ k, \ \text{result} \\
\text{result} := 1; \\
\text{for} \ k := 1 \ \text{step} \ 1 \ \text{until} \ j \do \\
\text{result} := \text{result} \times i; \\
\text{exp} := \text{result} \\
\text{end expi}
\end{align*}
\]

If \(n\) is of integer type and \(x\) of real type, then the value of \(x^n\) is given by the function:

\[
\text{real procedure} \ \text{exp}(x, n); \ \text{value} \ x, n;
\]

\[
x; \ \text{integer} \ n;
\]

\[
\text{if} \ n = 0 \ \land \ x = 0.0 \ \text{then}
\]

\[
\text{fault}(\text{exp}_{\uparrow\text{undefined}}, x)
\]

\[
\text{else}
\]

\[
\begin{align*}
\text{begin} \\
\text{real} \ \text{result}; \ \text{integer} \ i; \\
\text{result} := 1.0; \\
\text{for} \ i := \text{abs}(n) \ \text{step} \ -1 \ \text{until} \ 1 \do \\
\text{result} := \text{result} \times x; \\
\text{exp} := \text{if} \ n < 0 \ \text{then} \ 1.0/\text{result} \ \text{else} \ \text{result}
\end{align*}
\]

The call of the procedure \text{fault} denotes that the action of the program is undefined. It is understood that the finite deviations (see Section 3.3.6) of using the exponentiation operator may be different from those of using the procedures \text{exp} and \text{expn}.

### 3.3.4. Type of a conditional expression

The type of an arithmetic expression of the form

\[
\text{if} \ B \ \text{then} \ SAE \ \text{else} \ AE
\]

does not depend upon the value of \(B\). The expression is of real type if either \(SAE\) or \(AE\) is real and of integer type otherwise.

### 3.3.5. Precedence of operators

The sequence of operations within one expression is generally from left to right, with the following additional rules:

- **B.**
  - **first:** \(\uparrow\)
  - **second:** \(\times\) and \(\div\)
  - **third:** \(\pm\)

- **C.**
  - **first:** \(\uparrow\)
  - **second:** \(\land\), \(\lor\), \(\lnot\), \(\#\)

### 3.3.6. Arithmetics of real quantities

Numbers and variables of real type must be interpreted in the sense of numerical analysis, i.e. as entities defined inherently with only a finite accuracy. Similarly, the possibility of the occurrence of a finite deviation from the mathematically defined result in any arithmetic expression is explicitly understood. No exact arithmetic will be specified, however, and it is indeed understood that different implementations may evaluate arithmetic expressions differently. The control of the possible consequences of such differences must be carried out by the methods of numerical analysis. This control must be considered a part of the process to be described, and will therefore be expressed in terms of the language itself.

### 3.4. Boolean expressions

#### 3.4.1. Syntax

\[
\text{<relational operator>} ::= < | \le | = | \neq | > | \ge
\]

\[
\text{<relation>} ::= \text{<simple arithmetic expression>}\text{<relational operator>}\text{<simple arithmetic expression>}
\]

\[
\text{<Boolean primary>} ::= \text{<logical value>}\text{<variable>}
\]

\[
\text{<Boolean secondary>} ::= \text{<Boolean primary>} \lor \text{<Boolean primary>}
\]

\[
\text{<Boolean factor>} ::= \text{<Boolean secondary>} \land \text{<Boolean secondary>}
\]

\[
\text{<Boolean term>} ::= \text{<Boolean factor>} \lor \text{<Boolean factor>}
\]

\[
\text{<Boolean expression>} ::= \text{<Boolean term>} \lor \text{<Boolean term>}
\]

\[
\text{<if clause>} ::= \text{<simple Boolean>} \text{else} \text{<Boolean expression>}
\]

#### 3.4.2. Examples

\[
x = -2
\]

\[
y > z < q
\]

\[
a + b > -5 \land z - d > q/2
\]

\[
p \land q \lor x = y
\]

\[
g = \lnot a \land b \land c \lor d \lor e = \lnot f
\]

\[
\text{if} \ k < 1 \ \text{then} \ s > w \ \text{else} \ h \leq c
\]

\[
\text{if} \ a \ \text{then} \ b \ \text{else} \ c \ \text{then}
\]

\[
d \neq f \ \text{then} \ g \ \text{else} \ h < k
\]

#### 3.4.4. Types

Variables and function designators entered as Boolean primaries must be declared \text{Boolean} (see Section 5.1 Type declarations and Section 5.4.4 Values of function designators).

#### 3.4.5. The operators

The relational operators \(<, \leq, =, \geq, >, \neq\) and \# have their conventional meaning (less than, less than or equal to, equal to, greater than or equal to, greater than, not equal to). Relations take on the value \text{true} whenever the corresponding relation is satisfied for the expressions involved, otherwise \text{false}.

The meaning of the logical operators \(\lnot\) (not), \(\land\) (and), \(\lor\) (or), \(\equiv\) (implies), and \(=\) (equivalent), is given by the following function table:

<table>
<thead>
<tr>
<th>(\lnot)</th>
<th>(b1)</th>
<th>(b2)</th>
<th>(b1 \land b2)</th>
<th>(b1 \lor b2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{false}</td>
<td>\text{true}</td>
<td>\text{true}</td>
<td>\text{false}</td>
<td>\text{true}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>(b1 \equiv b2)</th>
<th>(b1 = b2)</th>
<th>(b1 \Rightarrow b2)</th>
<th>(b1 \Leftarrow b2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{true}</td>
<td>\text{true}</td>
<td>\text{true}</td>
<td>\text{true}</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>(b1 \Rightarrow b2)</th>
<th>(b1 = b2)</th>
<th>(b1 \Leftarrow b2)</th>
<th>(b1 \equiv b2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>\text{false}</td>
<td>\text{true}</td>
<td>\text{true}</td>
<td>\text{false}</td>
</tr>
</tbody>
</table>

#### 3.4.6. Precedence of operators

The sequence of operations within one expression is generally from left to right, with the following additional rules:

- **A.**

- **first:** \(\uparrow\)

- **second:** \(\land\), \(\lor\), \(\equiv\), \(\Rightarrow\), \(\Leftarrow\)

- **third:** \(\equiv\)

- **fourth:** \(\Rightarrow\)

- **fifth:** \(\Leftarrow\)

- **sixth:** \(\equiv\)

- **seventh:** \(\equiv\)
3.4.6.2. The use of parentheses will be interpreted in the sense given in Section 3.3.5.2.

3.5. Designational expressions

3.5.1. Syntax

\[
\text{\langle label \rangle ::= \langle identifier \rangle}
\]

\[
\text{\langle switch identifier \rangle ::= \langle identifier \rangle}
\]

\[
\text{\langle switch designator \rangle ::= \langle switch identifier \rangle\langle\langle\text{script expression}\rangle\rangle}
\]

\[
\text{\langle simple designational expression \rangle ::= \langle label \rangle}
\]

\[
\text{\langle switch designator \rangle\langle\langle\text{designational expression}\rangle\rangle}
\]

\[
\text{\langle designational expression \rangle ::= \langle simple designational expression \rangle}
\]

\[
\text{\langle if clause \rangle\langle\langle\text{simple designational expression}\rangle\rangle}
\]

\[
\text{\langle label \rangle::= \langle designational expression \rangle}
\]

3.5.2. Examples

\[
\begin{align*}
\text{\langle unlabelled block \rangle ::= (} & \langle block head \rangle; \langle\langle\text{compound tail}\rangle\rangle \text{\}) \\
\text{\langle unlabelled compound \rangle ::= begin & \langle\langle\text{compound tail}\rangle\rangle \text{\}}
\end{align*}
\]

\[
\langle\langle\text{compound tail}\rangle\rangle::= \langle\langle\text{begin \langle\text{compound statement}\rangle\rangle\langle\langle\text{block}\rangle\rangle\rangle\rangle & \langle\langle\text{dummy statement}\rangle\rangle\rangle
\]

\[
\langle\langle\text{begin \langle\text{compound statement}\rangle\rangle\langle\langle\text{block}\rangle\rangle\rangle\rangle::= \langle\langle\text{statement} & \langle\langle\text{block tail}\rangle\rangle\rangle\rangle
\]

\[
\langle\langle\text{statement} & \langle\langle\text{block tail}\rangle\rangle\rangle\rangle::= \langle\langle\text{unlabelled statement}\rangle\rangle\langle\langle\text{conditional statement}\rangle\rangle
\]

\[
\text{\langle label \rangle::= \langle designational expression \rangle}
\]

\[
\text{\langle block \rangle ::= \langle unlabelled block \rangle\langle\langle\text{label}\rangle\rangle\langle\langle\text{block}\rangle\rangle}
\]

\[
\text{\langle program \rangle ::= \langle block \rangle\langle\langle\text{compound statement}\rangle\rangle}
\]

This syntax may be illustrated as follows: Denoting arbitrary statements, declarations, and labels, by the letters \(S, D, \) and \(L\), respectively, the basic syntactic units take the forms:

\[
\text{\langle\langle\text{compound statement}\rangle\rangle::= \langle\langle\text{begin \langle\text{compound statement}\rangle\rangle\langle\langle\text{block}\rangle\rangle\rangle\rangle & \langle\langle\text{dummy statement}\rangle\rangle\rangle}
\]

\[
\langle\langle\text{begin \langle\text{compound statement}\rangle\rangle\langle\langle\text{block}\rangle\rangle\rangle\rangle::= \langle\langle\text{statement} & \langle\langle\text{block tail}\rangle\rangle\rangle\rangle
\]

\[
\langle\langle\text{statement} & \langle\langle\text{block tail}\rangle\rangle\rangle\rangle::= \langle\langle\text{unlabelled statement}\rangle\rangle\langle\langle\text{conditional statement}\rangle\rangle
\]

3.5.3. Semantics

A designational expression is a rule for obtaining a label of a statement (see Section 4 Statements). Again the principle of the evaluation is entirely analogous to that of arithmetic expressions (see Section 3.3.3). In the general case the Boolean expressions of the if clauses will select a simple designational expression. If this is the label this desired result is already found. A switch designator refers to the corresponding switch declaration (see Section 5.3 Switch declarations) and by the actual numerical value of its subscript expression selects one of the designational expressions listed in the switch declaration by counting these from left to right. Since the designational expression thus selected may again be a switch designator this evaluation is obviously a recursive process.

3.5.4. The subscript expression

The evaluation of the subscript expression is analogous to that of subscripted variables (see Section 3.1.4.2). The value of a switch designator this evaluation is obviously a recursive process.

3.6. Statements

The units of operation within the language are called statements. They will normally be executed consecutively as written. However, this sequence of operations may be broken by go to statements, which define their successor explicitly, shortened by conditional statements which cause certain statements to be repeated . In order to make it possible to define a specific dynamic succession, statements may be provided with labels.

Since sequences of statements may be grouped together into compound statements and blocks the definition of statement must necessarily be recursive. Also since declarations, described in Section 5, enter fundamentally into the syntactic structure, the syntactic definition of statements must suppose declarations to be already defined.

4.1. Compound statements and blocks

4.1.1. Syntax

\[
\text{\langle unlabelled basic statement \rangle ::= \langle assignment statement \rangle}
\]

\[
\langle go to statement \rangle\langle\langle\text{dummy statement}\rangle\rangle
\]

\[
\langle procedure statement \rangle
\]

\[
\text{\langle basic statement \rangle ::= \langle unlabelled basic statement \rangle}
\]

\[
\text{\langle label \rangle::= \langle basic statement \rangle}
\]

\[
\text{\langle unconditional statement \rangle ::= \langle basic statement \rangle}
\]

\[
\text{\langle compound statement \rangle ::= \langle block \rangle}
\]

\[
\text{\langle statement \rangle::= \langle unconditional statement \rangle\langle\langle\text{conditional statement}\rangle\rangle}
\]

\[
\text{\langle for statement \rangle::= \langle statement \rangle\langle\langle\text{end} & \langle\langle\text{block tail}\rangle\rangle\rangle\rangle
\]

\[
\langle block head \rangle::= \langle\langle\text{begin} & \langle\text{declaration}\rangle\rangle\langle\langle\text{block head}\rangle\rangle\langle\langle\text{declaration}\rangle\rangle
\]

4.2. Assignment statements

4.2.1. Syntax

\[
\text{\langle destination \rangle::= \langle variable \rangle\langle\langle\text{procedure identifier}\rangle\rangle
\]

\[
\text{\langle left part \rangle::= \langle destination \rangle}
\]

\[
\text{\langle left part list \rangle::= \langle left part \rangle\langle\langle\text{left part list}\rangle\langle\langle\text{left part}\rangle\rangle\rangle
\]

\[
\text{\langle assignment statement \rangle::= \langle left part list\rangle\langle\langle\text{arithmetic expression}\rangle\rangle\langle\langle\text{left part list}\rangle\langle\langle\text{Boolean expression}\rangle\rangle
\]

...
4.2.2. Examples

\[ s := p[0] := n := n + 1 + s \]
\[ n := n + 1 \]
\[ A := B(C - v - q \times S) \]
\[ S[v, k + 2] := 3 - \arctan(s \times zeta) \]
\[ V := Q > Y \land Z \]

4.2.3. Semantics

Assignments statements serve for assigning the value of an expression to one or several destinations. Assignment to a procedure identifier may only occur within the body of a procedure defining the value of the function designator denoted by that identifier (see Section 5.4.4). If assignment is made to a subscripts variable, the values of all the subscripts must lie within the appropriate subscript bounds. Otherwise the action of the program becomes undefined.

The process will in the general case be understood to take place in three steps as follows:

4.2.3.1. Any subscript expressions occurring in the destinations are evaluated in sequence from left to right.

4.2.3.2. The expression of the statement is evaluated.

4.2.3.3. The value of the expression is assigned to all the destinations, with any subscript expressions having values as evaluated in step 4.2.3.1.

4.2.4. Types

The type associated with all destinations of a left part list must be the same. If this type is Boolean, the expression must likewise be Boolean. If the type is real or integer, the expression must be arithmetic. If the type of the arithmetic expression differs from that associated with the destinations, an appropriate transfer function is understood to be automatically invoked. For transfer from real to integer type the transfer function is understood to yield a result which is the largest integer quantity not exceeding \( E + 0.5 \) in the mathematical sense (i.e. without rounding error) where \( E \) is the value of the expression. It should be noted that \( E \), being of real type, is defined with only finite accuracy (see Section 3.3.6). The type associated with a procedure identifier is given by the declarator which appears as the first symbol of the corresponding procedure declaration (see Section 5.4.4).

4.3. Go to statements

4.3.1. Syntax

\[ \langle \text{go to statement} \rangle ::= \text{go to} \langle \text{designational expression} \rangle \]

4.3.2. Examples

\[ \text{go to} \ L8 \]
\[ \text{go to} \ \text{exit}(n + 1) \]
\[ \text{go to} \ \text{Town} \{ \text{if} y < 0 \text{ then} N \text{ else} N + 1 \} \]
\[ \text{go to} \ \text{if} Ab < c \text{ then} L17 \]
\[ \text{else} \ q \{ \text{if} w < 0 \text{ then} 2 \text{ else} n \} \]

4.3.3. Semantics

A go to statement interrupts the normal sequence of operations, by defining its successor explicitly by the value of a designational expression. Thus the next statement to be executed will be the one having this value as its label.

4.3.4. Restriction

Since labels are inherently local, no go to statement can lead from outside into a block. A go to statement may, however, lead from outside into a compound statement.

4.3.5. Go to an undefined switch designator

A go to statement is undefined if the designational expression is a switch designator whose value is undefined.

4.4. Dummy statements

4.4.1. Syntax

\[ \langle \text{dummy statement} \rangle ::= \langle \text{empty} \rangle \]

4.4.2. Examples

\[ L: \begin{align*}
\text{begin} & \text{ statements; } \text{John: } \text{end}
\end{align*} \]

4.4.3. Semantics

A dummy statement executes no operation. It may serve to place a label.

4.5. Conditional statements

4.5.1. Syntax

\[ \langle \text{if clause} \rangle ::= \langle \text{if Boolean expression} \rangle \text{ then} \]
\[ \langle \text{unconditional statement} \rangle ::= \langle \text{basic statement} \rangle \]
\[ \langle \text{compound statement} \rangle ::= \langle \text{block} \rangle \]
\[ \langle \text{if statement} \rangle ::= \langle \text{if clause} \rangle \langle \text{unconditional statement} \rangle \]
\[ \langle \text{conditional statement} \rangle ::= \langle \text{if statement} \rangle \]
\[ \langle \text{if statement} \rangle \langle \text{else} \langle \text{statement} \rangle \rangle \]
\[ \langle \text{if clause} \rangle \langle \text{for statement} \rangle \]
\[ \langle \text{label} \rangle \langle \text{conditional statement} \rangle \]

4.5.2. Examples

\[ \text{if } x > 0 \text{ then } n := n + 1 \]
\[ \text{if } y > u \text{ then } V; q := n + m \text{ else go to } R \]
\[ \text{if } s < 0 \lor P \leq Q \text{ then } \]
\[ AA: \begin{align*}
\text{begin} & \text{ if } q < v \text{ then } a := v/s \\
\text{else} & \text{ y := } 2 \times a \\
\text{end}
\end{align*} \]
\[ \text{else if } v > s \text{ then } a := v - q \]
\[ \text{else if } v > s - 1 \text{ then go to } S \]

4.5.3. Semantics

Conditional statements cause certain statements to be executed or skipped depending on the running values of specified Boolean expressions.

4.5.3.1. If statement

An if statement is of the form

\[ \text{if } B \text{ then } Su \]

where \( B \) is a Boolean expression and \( Su \) is an unconditional statement. In execution, \( B \) is evaluated; if the result is \text{true}, \( Su \) is executed; if the result is \text{false}, \( Su \) is not executed. If \( Su \) contains a label, and a go to statement leads to the label, then \( B \) is not evaluated, and the computation continues with execution of the labelled statement.

4.5.3.2. Conditional Statement

Three forms of unlabelled conditional statement exist, namely:

- \( \text{if } B \text{ then } Su \)
- \( \text{if } B \text{ then } Sfor \)
- \( \text{if } B \text{ then } Su \text{ else } S \)

where \( Su \) is an unconditional statement, \( Sfor \) is a for statement and \( S \) is a statement.

The meaning of the first form is given in Section 4.5.3.1. The second form is equivalent to

\[ \text{if } B \text{ then begin } Sfor \text{ end} \]

The third form is equivalent to

\[ \begin{align*}
\text{begin} & \text{ if } B \text{ then begin } Su; \text{ go to } \Gamma \text{ end; } \\
\Gamma: & \text{ end}
\end{align*} \]

(For the use of \( \Gamma \) see Section 2.1 Letters.) If \( S \) is conditional, and also of this form, a different label must be used instead of \( \Gamma \) in following the same rule.

4.5.4. Go to into a conditional statement

The effect of a go to statement leading into a conditional statement follows directly from the above explanation of the execution of a conditional statement.

4.6. For statements

4.6.1. Syntax

\[ \langle \text{for list element} \rangle ::= \langle \text{arithmetic expression} \rangle \]
\[ \langle \text{arithmetic expression} \rangle \text{ step } \langle \text{arithmetic expression} \rangle \text{ until } \langle \text{arithmetic expression} \rangle \]
\[ \langle \text{arithmetic expression} \rangle \text{ while } \langle \text{Boolean expression} \rangle \]
\[ \langle \text{for list} \rangle ::= \langle \text{for list element} \rangle \langle \text{for list} \rangle \langle \text{for list element} \rangle \]
\[ \langle \text{for clause} \rangle ::= \langle \text{variable identifier} \rangle \langle \text{for list} \rangle \langle \text{for list element} \rangle \]
\[ \langle \text{for statement} \rangle ::= \langle \text{for clause} \rangle \langle \text{statement} \rangle \]
\[ \langle \text{label} \rangle :: \langle \text{for statement} \rangle \]
4.6.2. Examples

for \( q := 1 \) step 5 until \( n \) do \( A[q] := B[q] \)
for \( k := 1, V1 \times 2 \) while \( V1 < N \) do
for \( j := I + G, L, 1 \) step 1 until \( N, C + D \) do
\( A[k, j] := B[k, j] \)

4.6.3. Semantics

A for clause causes the statement \( S \) which it precedes to be repeatedly executed zero or more times. In addition it performs a sequence of assignments to its controlled variable (the variable after for). The controlled variable must be of real or integer type.

4.6.4. The for list elements

If the for list contains more than one element then

for \( V := X, Y \) do \( S \)
where \( X \) is a for list element, and \( Y \) is a for list (which may consist of one element or more), is equivalent to

\[
\begin{align*}
\text{begin} & \\
& \text{procedure} \Sigma; S; \text{end} \\
& \text{for} \ V := X \text{ do } \Sigma; \text{end} \\
& \text{for} \ V := Y \text{ do } \Sigma; \text{end}
\end{align*}
\]

(For the use of \( \Sigma \) see Section 2.1 Letters.)

4.6.4.1. Arithmetic expression element

If \( X \) is an arithmetic expression then

for \( V := X \) do \( S \)
is equivalent to

\[
\begin{align*}
\text{begin} & \\
& V := X; S; \text{end}
\end{align*}
\]

where \( S \) is treated as if it were a block (see Section 4.1.3).

4.6.4.2. Step-until element

If \( A, B \) and \( C \) are arithmetic expressions then

for \( V := A \) step \( B \) until \( C \) do \( S \)
is equivalent to

\[
\begin{align*}
\text{begin} & \\
& (\text{type of } B) \theta; \text{end} \\
& V := A; \text{end} \\
& \theta := B; \text{end} \\
& \Gamma; \text{end} \\
& \text{if} (V - C) \times \text{sign}(\theta) \leq 0 \text{ then} \\text{end} \\
& \text{begin} \text{begin} \\
& S; \text{end} \text{begin} \text{begin} \\
& V := V + \theta; \text{end} \text{begin} \text{begin} \\
& \text{go to } \Gamma' \text{end} \text{end} \text{end} \text{end}
\end{align*}
\]

where \( S \) is treated as if it were a block (see Section 4.1.3).

In the above, ('type of B') must be replaced by real or integer according to the type of \( B \). (For the use of \( \theta \) and \( \Gamma \) see Section 2.1 Letters.)

4.6.4.3. While element

If \( E \) is an arithmetic expression and \( F \) a Boolean expression then

for \( V := E \) while \( F \) do \( S \)
is equivalent to

\[
\begin{align*}
\text{begin} & \\
& \Gamma; \text{begin} \text{begin} \\
& V := E; \text{end} \text{begin} \text{begin} \\
& \text{if } F \text{ then} \text{end} \text{begin} \text{begin} \\
& S; \text{go to } \Gamma' \text{end} \text{end} \text{end} \text{end}
\end{align*}
\]

where both \( S \) and the outermost compound statement of the above expansion are treated as if they were blocks (see Section 4.1.3). (For the use of \( \Gamma \) see Section 2.1 Letters.)

4.6.5. The value of the controlled variable upon exit

Upon exit from the for statement, either through a go to statement, or by exhaustion of the for list, the controlled variable retains the last value assigned to it.

4.6.6. Go to leading into a for statement

The statement following a for clause always acts like a block, whether it has the form of one or not. Consequently the scope of any label within this statement can never extend beyond the statement.

4.7. Procedure statements

4.7.1. Syntax

\[
\begin{align*}
\langle \text{actual parameter} \rangle & ::= \langle \text{string} \rangle \langle \text{expression} \rangle \langle \text{array identifier} \rangle \\
& \langle \text{switch identifier} \rangle \langle \text{procedure identifier} \rangle \\
& \langle \text{letter string} \rangle ::= \langle \text{letter} \rangle \langle \text{letter string} \rangle \langle \text{letter} \rangle \\
& \langle \text{parameter delimiter} \rangle ::= \langle \text{string} \rangle \langle \text{letter} \rangle \\
& \langle \text{actual parameter list} \rangle ::= \langle \text{actual parameter} \rangle \\
& \langle \text{actual parameter list} \rangle \langle \text{parameter delimiter} \rangle \langle \text{actual parameter} \rangle \\
& \langle \text{actual parameter part} \rangle ::= \langle \text{empty} \rangle \langle \text{actual parameter list} \rangle \\
& \langle \text{procedure statement} \rangle ::= \langle \text{empty} \rangle \langle \text{actual parameter part} \rangle
\end{align*}
\]

4.7.2. Examples

\[
\begin{align*}
\text{Absmax}(A, N, M, Yy, 1, K) & \\
\text{Transpose}(W, v) & \\
\text{Innerproduct}(A[1, P, u], B[P, 10, P, Y])
\end{align*}
\]

These examples correspond to examples given in Section 5.4.2.

4.7.3. Semantics

A procedure statement serves to invoke (call for) the execution of a procedure body (see Section 5.4 Procedure declarations). Where the procedure body is a statement written in ALGOL the effect of this execution will be equivalent to the effect of performing the following operations on the program at the time of execution of the procedure statement:

4.7.3.1. Value assignment (call by value)

All formal parameters quoted in the value part of the procedure heading (see Section 5.4) are assigned the values (see Section 2.8 Values and types) of the corresponding actual parameters, these assignments being considered as being performed explicitly before entering the procedure body. The effect is as though an additional block embracing the procedure body were created in which these assignments were made to variables local to this fictitious block with types as given in the corresponding specifications (see Section 5.4.5). As a consequence, variables called by value are to be considered as non-local to the body of the procedure, but local to the fictitious block (see Section 5.4.3).

4.7.3.2. Name replacement (call by name)

Any formal parameter not quoted in the value list is replaced, throughout the procedure body, by the corresponding actual parameter, after enclosing this latter in parentheses if it is an expression but not a variable. Possible conflicts between identifiers inserted through this process and other identifiers already present within the procedure body will be avoided by suitable systematic changes of the formal or local identifiers involved.

If the actual and formal parameters are of different arithmetic types, then the appropriate type conversion must take place, irrespective of the context of use of the parameter.

4.7.3.3. Body replacement and execution

Finally the procedure body, modified as above, is inserted in place of the procedure statement and executed. If the procedure is called from a place outside the scope of any non-local quantity of the procedure body the conflicts between the identifiers inserted through this process of body replacement and the identifiers whose declarations are valid at the place of the procedure statement or function designator will be avoided through suitable systematic changes of the latter identifiers.

4.7.4. Actual-formal correspondence

The correspondence between the actual parameters of the procedure statement and the formal parameters of the procedure heading is established as follows: The actual parameter list of the procedure statement must have the same number of entries as the formal parameter list of the procedure declaration heading. The correspondence is obtained by taking the entries of these two lists in the same order.

4.7.5. Restrictions

For a procedure statement to be defined it is evidently necessary that the operations on the procedure body defined in Sections 4.7.3.1 and 4.7.3.2 lead to a correct ALGOL statement.

This imposes the restriction on any procedure statement that the
kind and type of each actual parameter be compatible with the kind and type of the corresponding formal parameter. Some important particular cases of this general rule, and some additional restrictions, are the following:

4.7.5.1. If a string is supplied as an actual parameter in a procedure statement or function designator, whose defining procedure body is an ALGOL 60 statement (as opposed to non-ALGOL code, see Section 4.7.8), then this string can only be used within the procedure as an actual parameter in further procedure calls. Ultimately it can only be used by a procedure body expressed in non-ALGOL code.

4.7.5.2. A formal parameter which occurs as a destination within the procedure body and which is not called by value can only correspond to an actual parameter which is a variable (special case of expression).

4.7.5.3. A formal parameter which is used within the procedure body as an array identifier can only correspond to an actual parameter which is an array identifier of an array of the same dimensions. In addition if the formal parameter is called by value the local array created during the call will have the same subscript bounds as the actual array.

Similarly the number, kind and type of any parameters of a formal procedure parameter must be compatible with those of the actual parameter.

4.7.5.4. A formal parameter which is called by value cannot in general correspond to a switch identifier or a procedure identifier or a string, because these latter do not possess values (the exception is the procedure identifier of a procedure declaration which has an empty formal parameter part (see Section 5.4.1) and which defines the value of a function designator (see Section 5.4.4). This procedure identifier is in itself a complete expression).

4.7.5.5. Restrictions imposed by specifications of formal parameters must be observed. The correspondence between actual and formal parameters should be in accordance with the following table.

<table>
<thead>
<tr>
<th>Formal parameter</th>
<th>Mode</th>
<th>Actual parameter</th>

</tbody>
</table>

If the actual parameter is, itself a formal parameter the correspondence (as in the above table) must be with the specification of the immediate actual parameter rather than with the declaration of the ultimate actual parameter.

4.7.6. Label parameters

A label may be called by value, even though variables of type label do not exist.

4.7.7. Parameter delimiters

All parameter delimiters are understood to be equivalent. No correspondence between the parameter delimiters used in a procedure statement and those used in the procedure heading is expected beyond their number being the same. Thus the information conveyed by using the elaborate ones is entirely optional.

4.7.8. Procedure body expressed in code

The restrictions imposed on a procedure statement calling a procedure having its body expressed in non-ALGOL code evidently can only be derived from the characteristics of the code used and the intent of the user and thus fall outside the scope of the reference language.

4.7.9. Standard procedures

Ten standard procedures are defined, which are declared in the environmental block in an identical manner to the standard functions. These procedures are: inchar, outchar, outstring, ininteger, inreal, outinteger, outreal, outterminator, fault and stop. The input/output procedures identify physical devices or files by means of channel numbers which appear as the first parameter. The method by which this identification is achieved is outside the scope of this report.

Each channel is regarded as containing a sequence of characters, the basic method of accessing or assigning these characters being via the procedures inchar and outchar.

The procedures inreal and outreal are converses of each other in the sense that a channel containing characters from successive calls of outreal can be re-input by the same number of calls of inreal, but some accuracy may be lost. The procedures ininteger and outinteger are also a pair, but no accuracy can be lost. The procedure outterminator is called at the end of each of the procedures outreal and outinteger. Its action is machine dependent but it must ensure separation between successive output of numeric data.

Possible implementation of these additional procedures are given in Appendix 2 as examples to illustrate the environmental block.

5. Declarations

Declarations serve to define certain properties of the quantities used in the program, and to associate them with identifiers. A declaration of an identifier is valid for one block. Outside this block the particular identifier may be used for other purposes (see Section 4.1.3).

Dynamically this implies the following: at the time of an entry into a block (through the begin since the labels inside are local and therefore inaccessible from outside) all identifiers declared for the block assume the significance implied by the nature of the declarations given. If these identifiers had already been defined by other declarations outside they are for the time being given a new significance. Identifiers which are not declared for the block, on the other hand, retain their old meaning.

At the time of an exit from a block (through end, or by a go to statement) all identifiers which are declared for the block lose their local significance.

A declaration may be marked with the additional declarator own. This has the following effect: upon a reentry into the block, the values of own quantities will be unchanged from their values at the last exit, while the values of declared variables which are not marked as own are undefined.

Apart from labels, formal parameters of procedure declarations, and identifiers declared in the environmental block, each identifier appearing in a program must be explicitly declared within the program.

No identifier may be declared either explicitly or implicitly (see Section 4.1.3) more than once in any one block head.

Syntax

\[
\langle\text{declaration}\rangle ::= \langle\text{type declaration}\rangle\langle\text{array declaration}\rangle
\]

\[
|\langle\text{switch declaration}\rangle|\langle\text{procedure declaration}\rangle
\]

5.1. Type declarations

5.1.1. Syntax

\[
\langle\text{type list}\rangle ::= \langle\text{simple variable}\rangle.|\langle\text{simple variable}\rangle,|\langle\text{type}\rangle
\]

\[
\langle\text{type}\rangle ::= \langle\text{real}\rangle|\langle\text{integer}\rangle|\langle\text{Boolean}\rangle
\]

\[
\langle\text{local or own}\rangle ::= \langle\text{empty}\rangle|\langle\text{own}\rangle
\]

\[
\langle\text{type declaration}\rangle ::= \langle\text{local or own}\rangle|\langle\text{type}\rangle
\]

5.1.2. Examples

integer \text{p}, \text{q}, \text{s}

\text{own Boolean Aeryl}, \text{n}

5.1.3. Semantics

Type declarations serve to declare certain identifiers to represent simple variables of a given type. Real declared variables may only
assume positive or negative values including zero. Integer declared variables may only assume positive and negative integral values including zero. Boolean declared variables may only assume the values true and false.

A variable declared own behaves as if it had been declared (and initialised to zero or false, see Section 3.1.5) in the environmental block, except that it is accessible only within its own scope. Possible conflicts between identifiers, resulting from this process, are resolved by suitable systematic changes of the identifiers involved.

5.2. Array declarations
5.2.1. Syntax
< array declarer > ::= < array segment > < array segment >

< array segment > ::= < local or own > < array declarer > < array list >

< array declarer > ::= < type > < array array >

< array array > ::= < bound pair list > < bound pair list >

< bound pair list > ::= < bound pair > < bound pair list >

< bound pair > ::= < lower bound > < upper bound >

< lower bound > ::= < arithmetic expression >
< upper bound > ::= < arithmetic expression >

< bound pair> ::= < lower bound > < upper bound >

5.2.2. Examples
array a, b, c[7:n, 2:m], s[-2:10]
own integer array A[2:20]
real array q[-7: if c < 0 then 2 else 1]

5.3.3. Semantics
A switch declaration defines the set of values of the corresponding switch designators. These values are given one by one as the values of the designational expressions entered in the switch list. With each of these designational expressions there is associated a positive integer, 1, 2, . . . , obtained by counting the items in the list from left to right. The value of the switch designator corresponding to a given value of the switch expression (see Section 3.5) is the value of the designational expression in the switch list having this given value as its associated integer.

5.3.4. Evaluation of expressions in the switch list
An expression in the switch list will be evaluated every time the item of the list in which the expression occurs is referred to, using the current values of all variables involved.

5.3.5. Influence of scopes
If a switch designator occurs outside the scope of a quantity entering into a designational expression in the switch list, and an evaluation of this switch designator selects this designational expression, then the conflicts between the identifiers for the quantities in this expression and the identifiers whose declarations are valid at the place of the switch designator will be avoided through suitable systematic changes of the latter identifiers.

5.4. Procedure declarations
5.4.1. Syntax
< formal parameter > ::= < identifier >

< formal parameter list > ::= < formal parameter > < formal parameter list >

< procedure declaration > ::= < procedure header > < procedure body >

< procedure header > ::= < procedure identifier > < specification part > < value part >

< specification part > ::= < empty >

< value part > ::= < value >

< empty > ::= < empty expression >
< value > ::= < value expression >

< value expression > ::= < empty expression >

5.4.2. Examples (see also the examples in Appendix 2)
procedure Spur(a) Order:(n) Result:(s); value n;
array a; integer n; real s;
begin integer k;
s := 0;
for k := 1 step 1 until n do s := s + a[k, k]
end

procedure Transpose(a) Order:(n); value n;
array a; integer n;
beg real w; integer i, k;
for i := 1 step 1 until n do
for k := 1 + i step 1 until n do
begin w := a[i, k];
a[i, k] := a[k, i];
a[k, i] := w
end
end

Transpose

integer procedure Step(u); value u; real u;
Step := if 0 ≤ u ∧ u ≤ 1 then 1 else 0

procedure Absmax(a) size:(n, m) Result:(y) Subscripts:(i, k);
value n, m; array a; integer n, m, i, k; real y;
comment The absolute greatest element of the matrix a, of size n by m
is transferred to y, and the subscripts of this element to i and k;
begin integer p, q;
y := 0; i := k := 1;
for p := 1 step 1 until n do
for q := 1 step 1 until m do
if abs(a[p, q]) > y then
begin \( y := \text{abs}(a[p, q]) \); \\
\( i := p \); \( k := q \)
end

**Procedure InnerProduct**

\text{begin}
\text{for } p := 1 \text{ step 1 until } k \text{ do } s := s + a \times b; \\
y := s
\text{end}
\text{InnerProduct}

\text{real procedure euler}(\text{fct}, \text{eps}, \text{tim}); \\
\text{value eps, tim;}
\text{real procedure fct; real eps; integer tim;}
\text{comment euler computes the sum of fct(i) for } i \text{ from zero up to infinity by means of a suitably refined euler transformation. The summation is stopped as soon as tim times in succession the absolute value of the terms of the transformed series are found to be less than eps. Hence one should provide a function fct with one integer argument, an upper bound eps, and an integer tim. euler is particularly efficient in the case of a slowly convergent or divergent alternating series;}
\text{begin}
\text{integer } i, k, n, r; \\
\text{array } m[0:15]; \\
\text{real mn, mp, ds, sum;}
\text{n := } i := 0; \\
m[0] := fct(0); \text{sum := } m[0]/2; \\
\text{for } i := 1, i + 1 \text{ while } i < \text{tim} \text{ do begin}
\text{mn := fct(i);} \\
\text{for } k := 0 \text{ step 1 until } n \text{ do begin}
\text{mp := } mn + m[k]/2; \\
m[k] := mn; mn := mp
\text{end means;}
\text{if abs(mn) } < \text{abs(m[n]) } \land n < 15 \text{ then begin}
\text{ds := mn} / 2; n := n + 1; \\
m[n] := mn
\text{end accept}
\text{else}
\text{ds := mn; sum := sum + ds;}
\text{t := if abs(ds) } < \text{eps then } t + 1 \text{ else 0}
\text{end; euler := sum}
\text{end euler}

5.4.3. Semantics
A procedure declaration serves to define the procedure associated with a procedure identifier. The principal constituent of a procedure declaration is a statement or a piece of code, the procedure body, which through the use of procedure statements and/or function designators may be activated from other parts of the block in the head of which the procedure declaration appears. Associated with the body is a heading, which specifies certain identifiers occurring within the body to represent formal parameters. Formal parameters in the procedure body will, whenever the procedure is activated (see Section 3.2 Function designators and Section 4.7 Procedure statements) be assigned the values of or replaced by actual parameters. Identifiers in the procedure body which are not formal will be either local or non-local to the body depending on whether they are declared within the body or not. Those of them which are non-local to the body may well be local to the block in the head of which the procedure declaration appears. The procedure body always acts like a block, whether it has the form of one or not. Consequently the scope of any label labelling a statement within the body or the body itself can never extend beyond the procedure body. In addition, if the identifier of a formal parameter is declared anew within the procedure body (including the case of its use as a label as in Section 4.1.3), it is thereby given a local significance and actual parameters which correspond to it are inaccessible throughout the scope of this inner local quantity.

No identifier may appear more than once in any one formal parameter list, nor may a formal parameter list contain the procedure identifier of the same procedure heading.

5.4.4. Values of function designators
For a procedure declaration to define the value of a function designator there must, within the procedure body, occur one or more uses of the procedure identifier as a destination; at least one of these must be executed, and the type associated with the procedure identifier must be declared through the appearance of a type declarator as the very first symbol of the procedure declaration. The last value so assigned is used to continue the evaluation of the expression in which the function designator occurs. Any occurrence of the procedure identifier within the body of the procedure other than as a destination in an assignment statement denotes activation of the procedure. If a go to statement within the procedure, or within any other procedure activated by it, leads to an exit from the procedure, other than through its end, then the execution, of all statements that have been started but not yet completed and which do not contain the label to which the go to statement leads, is abandoned. The values of all variables that still have significance remain as they were immediately before execution of the go to statement.

If a function designator is used as a procedure statement, then the resulting value is discarded, but such a statement may be used, if desired, for the purpose of invoking side effects.

5.4.5. Specifications
The heading includes a specification part, giving information about the kinds and types of the formal parameters. In this part no formal parameter may occur more than once.

5.4.6. Code as procedure body
It is understood that the procedure body may be expressed in non-ALGOL language. Since it is intended that the use of this feature should be entirely a question of implementation, no further rules concerning this code language can be given within the reference language.

Appendix 1 Subsets
Two subsets of ALGOL 60 are defined, denoted as level 1 and level 2. The full language is level 0. The level 1 subset is defined as level 0 with the following additional restrictions:

1. The own declarator is not included.
2. Additional restrictions are placed upon actual parameters as given by the following replacement lines to the table in Section 4.7.5.5.

<table>
<thead>
<tr>
<th>Formal parameter</th>
<th>Mode</th>
<th>Actual parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>name</td>
<td>integer expression (see 4.7.5.2)</td>
</tr>
<tr>
<td>real</td>
<td>name</td>
<td>real expression (see 4.7.5.2)</td>
</tr>
<tr>
<td>integer array</td>
<td>value</td>
<td>integer array (see 4.7.5.3)</td>
</tr>
<tr>
<td>real array</td>
<td>value</td>
<td>real array (see 4.7.5.3)</td>
</tr>
<tr>

<td>name</td>
<td>typeless procedure (see 4.7.5.3)</td>
</tr>
<tr>
<td>integer procedure</td>
<td>name</td>
<td>integer procedure (see 4.7.5.3)</td>
</tr>
<tr>
<td>real procedure</td>
<td>name</td>
<td>real procedure (see 4.7.5.3)</td>
</tr>
</tbody>
</table>

3. Only one alphabet of 26 letters is provided, which is regarded as being the lower case alphabet of the reference language.
4. If deleting every symbol after the twelfth in every identifier would change the action of the program, then the program is undefined.
5. The level 2 subset consists of restrictions 1-3 of level 1 and in addition:
6. Procedures may not be called recursively, either directly or indirectly.
7. If a parameter is called by name, then the corresponding actual parameter may only be an identifier or a string.
8. The specifiers switch, procedure and (type) procedure are not included.
9. A left part list may only be a left part.
10. If deleting every symbol after the sixth in every identifier would change the action of the program, then the program is undefined.
Appendix 2: The Environmental Block

As an example of the use of ALGOL, Appendix 2 illustrates the environmental block in detail.

begin

comment This description of the standard functions and procedures should be taken as definitive only so far as their effects are concerned. An actual implementation should seek to produce these effects in as efficient a manner as practicable. Furthermore, where arithmetics of real quantities are concerned, even the effects must be regarded as defined with only a finite accuracy (see Section 3.36). Thus, for example, there is no guarantee that the value of sqrt(x) is exactly equal to the value of \( \sqrt{0.5} \), or that the effects of inreal and outreal will exactly match those given here.

ALGOL coding has been replaced by a metalinguistic variable (see Section 1.1) in places where the requirement is clear, and there is no simple way of specifying the operations needed in ALGOL;

comment Environmental enquiries;
real procedure maxreal;
maxreal := ⟨number⟩;
real procedure minreal;
minreal := ⟨number⟩;
integer procedure maxint;
maxint := ⟨integer⟩;
comment maxreal, minreal, and maxint are, respectively, the
maximum allowable positive real number, the minimum allowable
positive real number, and the maximum allowable positive integer,
such that any valid expression of the form
⟨primary⟩⟨primary⟩( arithmetic operator)⟨primary⟩
will be correctly evaluated, provided that each of the primaries
concerned, and the mathematically correct result lies within the open
interval (−maxreal, −minreal) or (minreal, maxreal) or is zero
if of real type, or within the open interval (−maxint, maxint) if of
integer type.
If the result is of real type, the words 'correctly evaluated' must be
understood in the sense of numerical analysis (see Section 3.3.6);
real procedure epsilon;
comment The smallest positive real number such that the com­
putational result of 1.0 + epsilon is greater than 1.0 and the
computational result of 1.0 − epsilon is less than 1.0;
epsilon := ⟨number⟩;
comment In any particular implementation, further standard
functions and procedures may be added here, but no additional ones
may be regarded as part of the reference language (in particular,
a less rudimentary input/output system is desirable);
⟨fictitious declaration of own variables⟩;
⟨initialisation of own variables⟩;
⟨program⟩;
Ω.

Alphabetic index of definitions of concepts and syntactic units
All references are given through section numbers. The references are given in three groups:
def Following the abbreviation 'def', reference to the syntactic definition (if any) is given.
synt Following the abbreviation 'synt', references to the occurrences in metalinguistic formulae are given. References already quoted in the def-group are not repeated.
text Following the word 'text', the references to definitions given in text are given.
