The purpose of this manual is to give an informal introduction to the programming language BALM implemented on the CDC 6600 at the Courant Institute at New York University. This is a powerful language, possessing a number of highly sophisticated features, including vector, string, and list processing, programs as data, and extensibility.

CHAPTER 1. BASIC PROGRAM COMPONENTS

1.1 Variables, Values, Names, and Constants

A BALM program may refer to several kinds of data-objects. Some of these are constants which do not vary during the execution of the program. In this chapter we will deal mainly with integers. Constant integers can be written in the usual way. Examples of integer constants are

10, 246, -5.

Description of other types of data-object are postponed until Chapter 2.

Variables in a BALM program are used to refer to data-objects whose values can vary during the execution of the program. Each variable has a name, which is used to identify it, and a value, which may be changed by the execution of the program. The value of any variable can be any type of data-object which can be created by a BALM program. That is, in BALM a variable does not have a type associated with it, as in many other programming languages. In BALM the type of a data-object is determined by the data-object itself.

A variable name is written as a sequence of letters or digits starting with a letter. There are some exceptions which permit other characters to appear in names. But we shall postpone discussion of these for later chapters. Names with more than 8 characters are truncated by BALM with a warning message. Thus X, ABC, P1234 are all names of variables. ALONGNAME is also a variable but it would be seen by BALM as ALONGNAM. A variable can be given a new value in a number of ways, but the simplest is by use of an assignment expression. For example, the expression

ABC=123

would assign to the variable whose name was ABC the number 123 as its value. Subsequent references to ABC would then be taken to refer to this number, until its value was changed by a further assignment. The expression

XYZ19 = ABC

would assign to the variable whose name was XYZ19 the current value of the variable whose name is ABC.

1.2 Expressions and Values and Operators

Expressions are the most important components of a BALM program. A constant or a variable is an expression, and expressions can be combined with operators to make other expressions. Integer operators include multiply, divide, add, and subtract. The value of an expression is the value obtained by evaluating the expression using the current values of the variables. For example, if the value of the variable named ABC is 123, the value of the expression

ABC + 5

is the number 128, while the value of the expression

5 + ABC/3

is 46. The operators * and / are used to indicate multiplication and division respectively. The evaluation of an expression involving multiplication and addition is done so that the multiplication is done before the addition. In accordance with the ordinary rules of arithmetic, parentheses can be used to modify this order, so that the value of

(5 + ABC)/4

is 128/4, i.e. 32. That is, the expression inside parentheses is always evaluated first.

To give more flexibility in writing expression which are functions of more than two other expressions, the standard functional notation is used. For example

MAX(X+1,Y,2*Z)

is an expression whose value is given by applying the function named MAX to the values of the expressions X+1, Y, and 2*Z, which are referred to as the arguments of MAX. The same notation can be used for applying functions to one or two arguments, so that the expression:

SQRT(2*Z)

will have the value which will result from applying the function named SQRT to the value of the expression 2*Z.

In BALM there are functions which may have other effects than simply returning a result. The more general term procedure is usually used for such functions. In fact, some procedures may not even return any value, or may always return the same value. Such procedures are usually evaluated for their effect rather than their value. One such procedure in BALM is the PRINT procedure which will print out the values of its arguments and whose value is the value of its last argument. For example, execution of

PRINT(A+1)

will print out 21 if the value of A is 20.

In addition to facilities for manipulating integers, BALM can handle strings of characters, true and false, and various ways of specifying collections of these objects. For simplicity, however, we will restrict consideration for the time being to integers, which are very simple and familiar to most people.

1.3 Assignment

In BALM every expression has a value, though sometimes this value is inaccessible to the programmer. The assignment expression used above to show how a variable may receive a value is an expression whose value is the value of the expression used on the right-hand side of the = , and whose evaluation has the side-effect of assigning this value to the left-hand side. Evaluation of the right-hand side takes place before the assignment, so

COUNT= COUNT + 1

will take the current value of COUNT, add 1 to this value, and assign the result to the variable COUNT, thus increasing the value assigned to COUNT by 1. Note that

K = COUNT + 1

will use the value of COUNT to calculate the value of K, but will not change the value of COUNT. Since the assignment expression has a value, evaluation of the expression

A = (B = 1)

will have the value 1, and the side effect of assigning 1 to A and B.

1.4 Program Setup

BALM programs may either be punched on cards and submitted for batch processing or, if available at your installation, typed in at an interactive terminal. Suppose for the moment such a terminal is available and you have logged in and are ready to enter a BALM program. A semicolon after an expression is a signal to the BALM system to evaluate the expression it has just read, and then to read the next expression. Any line with an * in column 1 is treated as a comment.

Examples

Suppose the problem that we wish to solve is that of calculating the cost of painting a room. We can do this by calculating the area of the walls, and then multiplying this by the cost of the paint. For simplicity, suppose the room has one wall 8 by 16 and one wall 9 by 17, so we can find the area by typing in:

AREA = 8*16*9*17;
+

This will be executed, so we can then calculate the cost by multiplying the area by the cost per unit area, say 2 cents per square foot:

COST = 2*AREA;

and then printing out the result

PRINT(COST);

will print out 562 on the teletype. If we have \$7.00 to spend, we might then want to consider if we can also paint the closet, an additional area of 6 by 8. We can then type in:

PRINT(COST+2*6*8);

which will print out:

658

so we can make it, with 42 cents left for a beer.

If we don't have access to a teletype, we could have punched the same program on cards as follows:

```
* PROGRAM TO DETERMINE COST OF PAINTING A ROOM
AREA = 8*16*9*17;
COST = 2*AREA;
PRINT(COST);
PRINT(COST+2*6*8);
```

The output from the program would be printed on the line printer as the original program with a blank line separating the expressions, and with any printed output interspersed in the appropriate place. In the present example this would be as follows:

```
AREA = 8*16*9*17;
COST = 2*AREA;
PRINT(COST);
562
PRINT(COST+2*6*8);
658
```

1.5 Conditional Expressions

In very simple problems it is possible to write programs in which the expressions evaluated are independent of the data. In most interesting problems, however, this is not possible, and the programmer must be given some mechanism to permit the sequence of commands to be dependent on the values of expressions.

The usual way in which the course of the calculation can be made to depend on the objects being processed is by use of conditional expressions. These are usually of the form:

IF X THEN Y ELSE Z

where X is an expression whose value is to be tested, and Y and Z are arbitrary expressions. Expressions such as X are called logical expressions, and are considered to be false if their value is NIL, and true otherwise. If X is true, Y is evaluated, but if X is false, Z is evaluated.

There are a number of operators which can be used to construct logical expressions. In general, they return the value TRUE or NIL, and we will refer to them as predicates. The following predicates can be used to compare the values of two integers.

GT LT GE LE EQ NE

These are used to test if an integer is greater than, less than, greater than or equal to, less than or equal to, equal to, or not equal to another integer. For example

IF X EQ Y THEN Z=1 ELSE Z=2;

will set Z to 1 if X and Y have the same value, and to 2 otherwise. The value of a conditional is the value of the expression which is selected. For example,

Z = IF X EQ Y THEN 1 ELSE 2;

could have been written instead of the example above. Other predicate operators will be introduced later.

The ELSE clause can be left out, in which case the conditional behaves as if it had an

ELSE NIL

appended to it. For example

IF X EQ Y THEN Z=1;

will set Z to 1 if X and Y have the same value, and leave the value of Z unchanged otherwise.

An example of the use of simple conditionals is given in the program below, which does the calculations for the first nine lines of the New York State income tax form for 1969:

```

INCOME = 8000;
ADDITIONS = 200;
SUBTRACTIONS = 95;
TOTNYINC = INCOME + ADDITIONS - SUBTRACTIONS;
STANDED = TOTNYINC / 10;

IF STANDED GT 1000 THEN STANDED = 1000;
FITMDEDS = 950;
LIPREMS = 106;
ITAXDEDS = 500;
TOTITMDEDS = FITMDEDS + LIPREMS - ITAXDEDS;
IF STANDED GT TOTITMDEDS THEN DEDUCTIONS = STANDED
                           ELSE DEDUCTIONS = TOTITMDEDS;
NUMEXEMPTS = 3;
EXEMPTIONS = NUMEXEMPTS * 600;
NYTAXABLEINC = TOTNYINC - DEDUCTIONS - EXEMPTIONS;
PRINT(NYTAXABLEINC);

```

The random figures inserted are for a hypothetical resident who is married with one child (3 exemptions), earned \$8000 salary, with \$200 additional income and \$95 expenses, whose itemized deductions came to \$950 on his Federal return including \$500 in income tax deductions, and who paid \$106 in life insurance premiums. Of course the same program could be used for someone else simply by changing the appropriate figures. The two conditionals are inserted in accordance with the requirement that the standard deduction cannot exceed \$1000, and to insure that the resident gets the larger of two possible deductions.

The expression:

STANDED GT TOTITMDEDS

has the value true only if the value of STANDED is greater than the value of TOTITMDEDS.

If there are several alternatives to be selected, the following form of conditional can be used.

IF P1 THEN X1 ELSEIF P2 THEN X2 ELSEIF ... ELSE X

with the obvious interpretation.

Several conditions may be tested in one conditional by using the connectives AND and OR. For example

```

IF INCOME LT 3000 THEN TAX=0
ELSEIF INCOME LT 5000 AND NUMEXEMPT GT 4 THEN TAX=10
ELSEIF INCOME LT 10000 AND NUMEXEMPT GT 6 THEN TAX=20
ELSE TAX=30;

```

1.6 Loops

Most programming languages and computers recognize that the most useful kinds of algorithms contain sequences of instructions which are repeated many times. Special features are normally provided for permitting the construction and rapid execution of such repetitive sequences, which are usually referred to as loops.

In BALM there are two forms of loops provided. The first is called a while loop, and is of the form:

WHILE P REPEAT C

This is evaluated as follows.

1. The expression P is evaluated.
2. If the value is NIL, the while loop is finished.
3. The expression C is evaluated.
4. Go to step 1.

Note that the condition represented by P is evaluated at each step, so it is necessary that the evaluation of C be able to affect the value of P. The usual way of doing this is for C to contain an assignment which modifies a variable which is referenced in P.

For example, the following program will print out the smallest number whose square is greater than S:

```
I=1;  
WHILE I*I LE S REPEAT I=I+1;  
PRINT(I);
```

Suppose we only want to check the numbers up to some limit

```
I=1;  
WHILE I LT LIMIT AND I*I LE S REPEAT I=I+1;  
PRINT(I);
```

will terminate if I exceeds LIMIT or when the number whose square is greater than S is found.

The second kind of loop is the for-loop, which takes the following form:

FOR V=(I1,I2,I3) REPEAT C

where V stands for a variable, I1,I2,I3 stand for expressions whose values are integers, and C stands for an arbitrary expres-

sion. The action of the for loop is as follows:

1. The value of V is set to the value of I1.
2. The values of I2 and I3 are calculated.
3. If the value of V is greater than the value of I2 calculated in step 2, the for loop is finished.
4. The expression C is evaluated.
5. The value of V is increased by the value of I3 calculated in step 2.
6. Go to step 3.

As in the example, if I3 is left out, a value of 1 is assumed.

If I3 is negative, step 3 above tests for less than, and in step 5 V is decreased.

An example of a for loop is the following program which will calculate the value of $1*2*3\dots*N$ and put the result in NN:

```
NN = 1;
FOR I=(1,N) REPEAT NN = NN*I;
```

Note that, like all expressions, while loops and for loops have values. In each case the value of the loop is the value of the last C. Thus

```
NN = 1;
PRINT(FOR I=(1,N) REPEAT NN = NN*I);
```

will print out the final value assigned to NN.

Nesting of loops and conditional expressions give us the tools to evaluate some interesting problems.

```
FOR I=(1,1) REPEAT
  FOR J=(1,9) REPEAT
    FOR K=(1,9) REPEAT
      IF (I+J+K)*(I*J*K) EQ 100*I+10*J+K
      THEN PRINT(100*I+10*J+K)
```

will find all numbers between 1 and 199 whose value is equal to the sum of digits times the product of the digits. Of course, this is a rather inefficient method. We shall see how the use of compound expressions increases our capabilities.

1.7 Compound expressions

A useful form of expression which can be used with loops and conditionals permits several expressions which are to be evaluated in sequence to be written as a single expression. The form of this is

```
DO C1,C2, ... CN END;
```

where C1,C2...,CN are expressions. Expressions within a compound expression are separated by commas. An example of this is

```
NN = 1; I = 1;  
WHILE I LE N REPEAT DO NN = NN*I, I = I+1 END;
```

I LE N is an expression which is true as long as I is less than or equal to N.

The value of a compound is the value of the last expression before the end. A compound expression may occur anywhere a single expression could appear.

Example 1.7.1

Although we still have not introduced the more powerful properties of BALM, it is possible at this point to solve some fairly interesting problems. The following program, for instance, will print out all the triples X,Y,Z of numbers below 100, for which $X^2 + Y^2 = Z^2$.

```
FOR Z=(1,100) REPEAT DO ZZ=Z★Z,  
  FOR Y=(1,Z-1) REPEAT DO YY=Y★Y,  
    FOR X=(1,Y) REPEAT  
      IF X★X+YY EQ ZZ THEN  
        PRINT(X,Y,Z)  
    END  
  END;
```

The reader should note that the values taken on by X, Y and Z for successive executions of the conditional start out with

1,1,2 1,1,3 1,2,3 2,2,3 1,1,4 and so on.

If this seems confusing the reader should consider that a loop is not executed if the initial value is greater than the limit. Consider the case when Z=1. Then the loop beginning for Y=(1,Z-1) will be skipped, and Z=2 will be the next value. This is by no means the perfect program for doing this -- for example, we know that if $X^2 + Y^2 = Z^2$ then $X+Y$ is greater than Z so there is no point in testing values of X which are less than Z-Y. The

adjustments of the above program to accomplish this are left to the reader. There are, of course, many other ways of solving the above problem which the reader could implement at this point.

1.8 Blocks

A block in its simplest form has the following structure

```
BEGIN(V1,...,VN),X1,...,XM END
```

where V1,...,VN are variables which are to be considered local to the block, and X1,...,XM are expressions. In this form a block is similar to a compound, in that the expressions X1,...,XM are executed in order, with the value of the block being the value of XM. Variables used in the block which are not declared to be local are called global. Usually blocks can be included in other blocks, so variables which are local to an outer block may be global to an inner block. For example, the following extract from a program would print out the value 6:

```
X = 1; Y = 10;  
BEGIN(X), X = 5, Y = 5 END;  
PRINT(X+Y);
```

The variable X inside the block is declared local, so the assignment to X will not affect the X which has been assigned the value 1. The variable Y, however, is global to the block, and so its value is changed to 5.

The value of being able to declare local variables will be more clear when we discuss user defined procedures. In many languages, FORTRAN for example, variables are always local unless they are specifically declared global by appearing in a COMMON statement. In BALM we have just the opposite case. We will however postpone further discussion until the section on name scoping.

1.8.1 Labels and Gotos

In the examples we have given so far, our program has simply consisted of a number of expressions which were to be evaluated in the order in which they were written. We will now consider how this order can be controlled in a more flexible way.

Suppose we have a number of expressions whose evaluation order we wish to specify. In BALM we can do this by grouping them into a block, and inserting extra expressions to specify the execution order. We will call these jumps. If no jumps are specified, the expressions will be evaluated in the order they are written.

For example

```
AREA = 8*16*9*17;  
COST = 2*AREA;  
PRINT(COST);
```

could be written

```
BEGIN(),  
AREA = 8*16*9*17,  
COST = 2*AREA,  
PRINT(COST)  
END;
```

This would have the same effect, but if it was being typed on a teletype nothing would be executed until the user typed in the semicolon.

When expressions are grouped in a block we may transform from one expression to another.

The simplest kind of jump in BALM is of the form

```
GOTO L
```

where L is a name. When evaluated, this will cause the next expression to be evaluated to be the one immediately following the name L in the list of expressions. Such a use of a name is called a label. For example

```
BEGIN(),  
MOR, I = 10*I,  
J = I+2,  
GOTO MOR  
END;
```

would not terminate, or not at least until stopped by the computer operator. Each time the GOTO was evaluated, evaluation would continue with the expression following MOR.

Jumps are usually used in close conjunction with conditionals. This permits the execution of the jump to be dependent on the value of some expressions, and so permits the sequence of evaluation to be dependent on the data supplied to the program. In particular, the use of conditional jumps permits the programmer to write more complex loops than are provided by the for-loop and while-loop expressions.

As an example of a program which uses loops, let us consider the program which will print out the perfect numbers below 100. A perfect number is defined as a number which is the sum of the numbers which divide it exactly. The ancient Greeks knew of the existence of perfect numbers, one of which is the number 6, which is exactly divisible by 1, 2, and 3. The program can be written as follows:

```
BEGIN(),
I=1,
NXT, J=2, S=1,
NXJ, IF J GE I THEN GOTO FIN,
Q=I/J,
IF I EQ J*Q THEN S=S+J,
J=J+1,
GOTO NXJ,
FIN, IF I EQ S THEN PRINT(I),
I=I+1,
IF I LT 100 THEN GOTO NXT
END;
```

Jumps may only take place within a block. BALM does not permit us to transfer from one block to another. Thus

```
BEGIN(),
PRINT(10+20),
GOTO DONE
END;
```

is invalid since it implies transfer to a label not defined in the block.

Labels are only valid within blocks and may not occur within compound expressions or conditional expressions. Thus

```
BEGIN(),
I=1,
NXT, I=I+1,
IF I/2*2 EQ I THEN PRINT(I),
IF I LT 100 THEN GO NXT
END;
```

is valid but

```
BEGIN(),
FOR I=(1,100) REPEAT DO
NXT, IF I/2*2 EQ I THEN PRINT(I) ELSE GOTO NXT
END END;
```

is an invalid use of a label and will result in a run time diagnostic because labels may not appear within a compound.

Indirect Jumps

In an expression of the form GOTO X, X can be an arbitrary expression whose value is a label. X could have been set, for example, to a label prior to execution of the GOTO, as in the following

```
BEGIN(L),
  IF SWITCH EQ 4 THEN L=L1
  ELSEIF SWITCH EQ 3 THEN L=L2
  ELSEIF SWITCH EQ 2 THEN L=L3
  ELSE L=L4,
  GOTO L,
L1, ...
L2, ...
L3, ...
L4, ...
END;
```

More uses of this facility are possible using the more powerful data-objects which are described in chapter 2.

1.8.2 Use of RETURN

In BALM a block is an expression and has as its value the value of the last expression evaluated. The operator return can be used to terminate the evaluation of the expressions in the block, and to give it a value. For example, code to assign to R the value of factorial N can be written

```
R = BEGIN(I,NN),
  NN=1, I=1,
  NXT, IF I GT N THEN RETURN NN;
  NN=NN*I,
  I=I+1,GOTO NXT
END;
```

RETURN causes a skip to the end of the block and can be thought of as a block exit. The value returned becomes the value of the entire block. In a later section we will show how the user can write code which will permit him to write:

```
R=FACT(N);
```

which is more convenient.

EXERCISES

- 1.1 Write a program to convert numbers less than 100 from decimal to octal.
- 1.2 Rewrite example 1.7.1 so that values of X which are less than Z-Y are not tested. Compare the running times.

CHAPTER 2. MANIPULATION OF DATA OBJECTS AND STRUCTURES

2.1 General Properties of Data Objects

The objects which can be manipulated by a BALM program are called items. Each item has a type, which is one of the following.

logical
integer
label
pointer-to-identifier
pointer-to-code
pointer-to-string
pointer-to-pair
pointer-to-vector

For convenience, we will often delete the pointer-to prefix and refer to a pointer-to-vector, for example, simply as a vector. A pointer-to-code is usually called a procedure. The last three types of item, strings, pairs and vectors, are themselves ordered sets of items, while the other types can be considered to be more primitive.

All items in BALM are treated uniformly, in the sense that any item can be assigned as the value of any variable, given as an argument of a procedure, or returned as the value of a procedure call. This is in contrast to many other programming languages, in which a variable is restricted to have a particular type of item as its value. In BALM the type of an item is determined by the item itself rather than the variable whose value it is.

The following expressions can be used to test the type of an item.

<u>Expression</u>	<u>Value</u>
PAIRQ(X)	TRUE if X is a pair, NIL otherwise
VECTQ(X)	TRUE if X is a vector, NIL otherwise
IDQ(X)	TRUE if X is an identifier, NIL otherwise
INTQ(X)	TRUE if X is an integer, NIL otherwise
LOGQ(X)	TRUE if X is true or NIL, NIL otherwise
LBLQ(X)	TRUE if X is a label, NIL otherwise
CODEQ(X)	TRUE if X is code, NIL otherwise
STRQ(X)	TRUE if X is a string, NIL otherwise
X SIM Y	TRUE if X and Y are of the same type, NIL otherwise.

These take an arbitrary item as argument, and have the value true if the item is the specified type, and nil otherwise. For example, to take an action which is dependent on the type of X, we can write code of the form

IF INTQ(X) THEN .., ELSEIF PAIRQ(X) THEN ...

Note that all types are mutually exclusive, so that if a particular item satisfies one type test, it cannot also satisfy a different one. The operator

SIM

can be used to test if two items have the same type, so that

P(X,Y) SIM 123

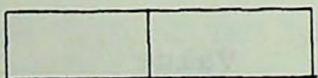

has the same value as

INTQ(P(X,Y))

The three forms of item which can be used to represent ordered sets have different characteristics and different uses, which we will be outlining in the rest of this chapter. Of these, the string is the simplest, consisting of an ordered set of characters (letters and digits etc.). The vector and the list are more powerful, being ordered sets of arbitrary items (including other vectors and lists).

2.2 Internal Representation

In the diagrams below we show informally how items could be represented in memory in a typical implementation. Items are as boxes of the form

Each such box represents an item, and contains a type field and a value field, which may contain a pointer. Boxes shown on top of each other will usually be adjacent in memory.

(PROPERTY
LIST)

Labels and logicals have the same internal representation as integers. Code blocks have the same internal representation as strings.

In addition in some implementations a third field called mode is present. On the 6600 this field is 6 bits long and may be set to an integer between 0 and 7.

TYPE	MODE	
------	------	--

The following operations are available to manipulate the mode field.

EXPRESSION	VALUE
MODE(X)	returns as an integer the mode field of X (6 bits on the CDC 6600 implementation)
SETMODE(X,I)	the item X with mode field set to I

2.3 Atomic Items

Integers, identifiers, labels and logicals are atomic in that the item contains the data rather than a pointer to it. We shall discuss code along with the atomic items even though a code item contains a pointer to a code block. This is because there are no BALM operations which modify code blocks.

2.3.1 Integers

Integers may be expressed as decimal or octal numbers in BALM. Any integer followed by a B is interpreted as being octal. For example

13 -75 10101

are decimal integers, while

77B 101010B 10B

are all octal numbers.

The following expressions may be used with integers.

<u>Expression</u>	<u>Value</u>
I+J	
I-J	
I*J	
I/J	
-I	
I ^J	I raised to the J-th power
I EQ J	
I ≡ J	same as I EQ J
I NE J	
I LT J	
I GT J	
I LE J	
I GE J	
LAND(I,J)	bit by bit AND of I and J I and J are considered as binary numbers
LOR(I,J)	bit by bit OR of I and J
COMPL(I)	complement of I
XOR(I,J)	exclusive OR of I and J
SHIFT(I,J)	left rotate of I by J places when J is positive right algebraic shift with sign extension if J is negative
PL I	TRUE if I is not negative, NIL otherwise
ZR I	TRUE if I is zero, NIL otherwise

Integers on the CDC 6600 version are 18 bits long.

A SHIFT(I,18) results in I and a SHIFT(I,-18) in 0.

Note: Decimal integers must be of magnitude less than 131,072.

2.3.2 Logicals

Logicals are TRUE and NIL. For convenience NIL and FALSE are the same. The following expressions may be used with logical items.

<u>Expression</u>	<u>Value</u>
X AND Y	if X then Y else NIL
X OR Y	if $\neg X$ then Y else TRUE
NOT X	if X then NIL else TRUE
NULL X	if X then NIL else TRUE
$\neg X$	if X then NIL else TRUE

The reader should note that the above expressions test for a value of NIL. Any value other than NIL will be interpreted in the same way as TRUE.

2.3.3 Identifiers

An identifier may be thought of as an ordered triple, whose components are called name, value and property-list. The name component is always a string, while the value and property-list components may be of arbitrary type. Names of identifiers may be only eight characters long and will be truncated with a warning message if they exceed eight characters.

Constant identifiers used as data-objects may be specified by a name preceded by a quote to distinguish them from their values. Either _ or = may be used as a quote. Thus

_ABC =XYZ _ALONGNAME

are valid identifiers. Note that ABC without the quote would normally refer to the value of the variable ABC.

The following expressions may be used with identifiers.

<u>Expression</u>	<u>Value</u>
SFROMID(ID)	the string which is the name component of ID thus SFROMID(<u>_</u> ABC) results in ≠ABC≠
VALUE ID	the value component of ID For example: X=VALUE(=ABC) is equivalent to X=ABC
PROPL(ID)	the property-list component of ID We shall discuss property lists in more detail when we discuss language extensions. An identifier may have a property or properties as well as a value.
VALUE ID = X	has the value X and the side-effect of changing the value component of ID to X
PROPL(ID) = X	has the value X and the side-effect of changing the property-list component of ID to X
ID1 EQ ID2 ID1 ≡ ID2	TRUE if ID1 and ID2 are the same identifier, NIL otherwise.

2.3.4 Code Blocks

Code blocks in BALM are the items used to represent procedures. Both the BALM system procedures and user-defined procedures are represented as code blocks. Each time the BALM compiler encounters a semicolon it generates a block of code and then executes it.

The following expressions can be used with code.

<u>Expression</u>	<u>Value</u>
CFROMV(V)	The block of code corresponding to the instructions specified as integers in the vector V.
IDFROMC(C)	The identifier which appeared on the left-hand side when the block of code was defined as a procedure (see Chapter 3).
APPLY(C,X)	returns the value of procedure C when applied to argument X, if X is a list (see Section 2.6) it is considered to be a list of arguments and C will be applied to the members of the list. If X is not a list it is considered to be the sole argument of C.
C1 EQ C2	TRUE if C1 and cC2 refer to the same code block;
C1 ≡ C2	NIL otherwise.

2.3.5 Labels

Labels are used with GOTOS to determine the flow of control of the program. Constant labels are defined by using an identifier as described in Section 1.8.1. This identifier can be thought of as a local variable of the block whose value is the label item.

The following expressions can be used with labels.

<u>Expression</u>	<u>Value</u>
GOTO L	Value is not accessible to the programmer, control is transferred to the instruction at L, L may be an arbitrary expression, but its value must be a label defined in the current block.
GO L	

2.4 Strings

A string in BALM is an ordered set of characters, where we use the term character to refer to those symbols which can be punched on a card or typed on a teletype. Strings may be of arbitrary length, and may contain arbitrary characters. A constant string is specified in a program by preceding the first character by the symbol # and following the last character by the symbol #.

In order to include the character # in a string it must appear twice. For example

S1=****

is the string consisting of one character which is #.

S2=*A QUOTE ** MAY APPEAR IN A STRING*;

will print as

*A QUOTE * MAY APPEAR IN A STRING*;

The primitive operations on strings provided in BALM include facilities for extracting part of a string (a substring), and for changing a substring. The operator sub used for this purpose takes three arguments, a string, the index of the first character of the substring, and the length of the substring. Thus

Thus the program

S = *ABCDEFGHI12345*; SS = SUB(S,3,4);
SUB(S,5,7) = *+++*

will assign the string #CDEF# to the variable SS, and leave the string #ABCD+++345# as the value of the variable S.

Strings may be concatenated using the operator concat. For example

PRINT(CONCAT(*ABC*,*1234567890123*));

will print #ABC1234567890123#.

The following expression may be used to create a string.

<u>Expression</u>	<u>Value</u>
STRING(I1,I2,...,IN)	the string whose characters are represented by I1,I2,...,IN .

This is only useful when the user knows the integer representation of the character. For example:

STRING(1,2,3);

results in #ABC#.

The reader should note that the variable whose name is ABC is not the same thing as the string ABC. However, the BALM system does permit one to be converted to the other.

The following expressions may be used with strings.

<u>Expression</u>	<u>Value</u>
SIZE S	the number of characters in S
IDFROMS (S)	the unique identifier in the system whose name is S. For example: IDFROMS(#ALONGNAME#) has ALONGNAM as its value. Note that the string is truncated to 8 characters.

[continued]

<u>Expression</u>	<u>Value</u>
VFROMS(S)	creates a new vector whose elements are the integer representations of the characters of S (see Section 2.5).
CONCAT(S1,S2)	creates a new string whose characters are the same as S1 followed by S2
SUB(S,I,J)	creates a new string whose characters are the I-th through the (I+J-1)-st character of S
SUB(S1,I,J)=S2	has the value of S2 and the side effect of changing the I-th through the (I+J-1)-st characters of S1 to the first through the J-th characters of S2
S1 EQ S2	TRUE if S1 and S2 refer to the same string,
S1 ≡ S2	NIL otherwise
EQSTR(S1,S2)	returns TRUE if S2 is the same as or a copy of S1; otherwise NIL.

If a string exceeds 1 line, trailing blanks are deleted.

For example

*A STRING
ON TWO LINES*

is equivalent to

A STRINGON TWO LINES

2.4.1 Copying and Assignment

In addition to these operations a series of useful procedures and functions are part of the BALM system. They are listed in entirety in Appendix E. PRINT is one such procedure which we have discussed previously. Below we will describe COPY.

In BALM the assignment operation is done by assigning a copy of the item which is the value of the right-hand side to the left-hand side. However, in the case of a pointer-to type only the pointer is copied, not the object pointed to. In a similar way, arguments to procedures are copies of the actual arguments, but in the case of pointer-to items only the pointer is copied. For example:

```
A=10;
SAVE=A;
A=A+1;
PRINT(SAVE);
10
```

Changing the value of A does not affect SAVE. Consider, however, what happens when the item is not atomic and contains instead a pointer to a data structure. For example:

```
ALPHA=#ABCDEFGHIJKLMNOPQRSTUVWXYZ#  
MOD=ALPHA;  
SUB(MOD,2,3)=#234#;  
PRINT(MOD);  
#A234EFGHIJKLMNOPQRSTUVWXYZ#  
PRINT(ALPHA);
```

The value of ALPHA is also #A234EFGHIJKLMNOPQRSTUVWXYZ#. Two things should be noted about the above example: (1) the expression MOD=ALPHA sets MOD to an item whose type is string and whose value is a pointer to the same data structure referred to by ALPHA. In other words the structure representing #ABCDE.....# occurs only once in memory but the assignment created a second reference to it. (2) The expression SUB(MOD,2,3)=#234# has the side effect of changing the representation in memory. Since the structure only exists once any item referencing it reflects the change.

COPY is a function which returns a copy of its argument. If the assignment expression in the above example were changed to: MOD=COPY(ALPHA); then MOD would contain a reference to a string containing the same characters as ALPHA but not represented in memory by the same structure as ALPHA.

2.5 Vectors

A vector in BALM is an ordered set of items in which an element of the set is referred to by specifying its position within the vector. For example, if the value of the variable V is a vector the first element of the vector is referred to by the expression V(1), the second by V(2), etc. The integer used to specify the element is usually called an index, and in BALM it can be a constant, a variable, or an expression of arbitrary complexity.

A piece of program which will assign to the variable M the largest number in a vector V whose elements are all numbers can be written

```
L=LENGTH(V);  
M=V(1);  
FOR I=(2,L) REPEAT  
IF V(I) GT M THEN M=V(I);
```

Here we have used the procedure LENGTH which will return as its value the number of items in the vector (or list or string) given as its argument.

An element of a vector can have its value changed by an assignment in which the left-hand side specifies the element. For example, the following piece of program will reverse the order of the elements of the vector V.

```
L = LENGTH(V);
FOR I=(1,(L+1)/2) REPEAT
    DO S=V[I], V[I]=V[L+1-I], V[L+1-I]=S END;
```

As a more complicated example, we give below a piece of program which will sort a vector V of numbers into increasing order.

```
L = LENGTH(V);
FOR I=(1,L-1) REPEAT
    IF V[I] GT V[I+1] THEN DO
        X = V[I+1], V[I+1] = V[I], J = I,
        WHILE J GE 2 AND V[J-1] GT X REPEAT DO
            V[J] = V[J-1], J = J-1 END,
        V[J] = X
    END;
```

This way of implementing the sorting operation is called a bubble sort. Essentially the algorithm looks at successive pairs of elements, checking to see if they are in the correct order. When an incorrectly ordered pair is found, the second element is moved backwards towards the beginning of the vector until it is in the correct position, all the intervening elements being moved forward one place. The search for incorrectly ordered pairs is then continued. When the last pair has been examined, the vector elements are in the correct order. The reader should trace through this program with a sample vector to check that he follows the logic.

A vector can be created in BALM in several ways. The simplest uses the operator VECTOR, which can have an arbitrary number of arguments, and which will return as its value the vector which has as its elements the values of those arguments. Thus

```
ABC = VECTOR(A+B,12,MAX(V))
```

will assign to the variable ABC the 3-element vector whose elements are the value of A+B, the number 12, and the maximum element in the vector V, in that order. Alternatively we can use the procedure MAKVECTOR to create a vector of specified size, but without assigning particular values to the elements (they will all be set to NIL).

actually). Thus

```
DO ABC = MAKVECTOR(3), ABC[1] = A+B,  
    ABC[2] = 12, ABC[3] = MAX(V) END;
```

would have precisely the same effect as the single expression above.

The following expressions can be used to create vectors.

<u>Expression</u>	<u>Vector</u>
VECTOR(X1,X2,...,XN)	a vector whose elements are X1,X2,...,XN
MAKVECTOR(I)	a vector with I undefined elements

In the above examples, the only expressions we have used with indices have been simple variables. In fact any expression whose value is a vector can be indexed. One very useful data-structure is a vector whose elements are themselves vectors -- sometimes called a two-dimensional array in other programming languages or a matrix by mathematicians. If M is such a data-structure then the 3rd element is M[3], and the 2nd element of its 3rd element is M[3][2]. This element can be changed by putting this expression on the left-hand side of an assignment in the usual way.

In BALM a simple notation is available for printing a vector. This is illustrated by the program

```
V = VECTOR(12, 34, 56); PRINT(V);
```

which would print

```
[12 34 56]
```

In more elaborate cases, such as when the elements of the vector are themselves vectors or other complex data-structures, an extension of the notation is used. In general, a vector is printed as a left square bracket followed by the appropriate notation for the vector elements, separated by spaces, and terminated by a right square bracket.

This same notation can also be used to specify constant vectors in the program. When used in this way, the vector should be preceded by a quote operator which distinguishes this use of the square brackets from others. We use `>` or `=` as a quote.

```
V ==[12 34 56]
```

will actually have the same effect as the assignment to V given above. A vector constant may not contain variables. Identifiers appearing in a vector constant are treated as identifier constants.

even though they are not preceded by a quote. Thus
is equivalent to
and both will print as

```
V=>[A B C];
V=VECTOR(>A,>B,>C));
[A B C]
```

Similarly

```
V1=>[X Y Z];
X=10; Y=20; Z=30;
V2=VECTOR(X,Y,Z);
X=>A NEW VALUE<;
PRINT(V1); PRINT(V2);
```

will print

```
[X Y Z]
[10 20 30]
```

The following expressions may be used with vectors.

<u>Expression</u>	<u>Value</u>
V[I]	the I-th element of V
V[I] = X	has the value X and the side-effect of changing the I-th element of V to X
SIZE V	the number of elements in V
CONCAT(U,V)	the vector whose elements are U(1),...,U[SIZE U],V[1],...,V[SIZE V]
SUB(U,I,J)	the vector whose elements are U[I],...,U[I+J-1]
SUB(U,I,J)=V	has the value V and the side-effect of changing the I-th through (I+J-1)-st elements of U to V[1],...,V[J]
SFROMV(V)	the string whose characters are represented by the elements of V, assumed to be integers less than 128
CFROMV(V)	the code corresponding to the elements of V, assumed to be integers less than 128
V EQ U	TRUE if V and U point to the same vector,
V ≡ U	NIL otherwise
COPY(V)	described in the previous section. COPY can also be used with vectors and makes a copy of all elements of V, and all their elements, etc. The reader should note that two vector operations V[I]=X and SUB(U,I,J)=V have side effects which result in the data structure being changed.

[continued]

EQUAL(X1,X2)	Any items which reference a vector are affected by $V[I]=X$ and $SUB(U,I,J)=V$. a utility procedure which returns TRUE if X2 is the same as or a copy of X1, NIL otherwise.
---------------------	---

With the availability of vectors, the range of problems that we can conveniently solve is considerably increased. Many objects which require a number of properties for their description can be conveniently represented by vectors whose elements are the values of those properties. For instance, a triangle can conveniently be represented by a vector of length three, whose elements are the lengths of its sides, and the position of a town can be represented by its latitude and longitude. Since in BALM a vector can itself be an element of a vector, we can represent a trip across the country by a vector whose elements are the 2-element vectors representing the positions of the towns on the route.

In some algorithms, it is found to be convenient to be able to have other types of operations as the basic primitives for manipulating ordered sets. For example, an algorithm which frequently requires that an element be added to or deleted from an ordered set will be rather inefficient using vectors. For this reason we provide an alternative data-structure capable of representing general ordered sets, but in which the primitive operations are different. We refer to these data-structures as lists, which are described in more detail in the next section.

2.6 Pairs

A pair is an ordered pair of items, the first component being called head and the second component tail. Any two items may be combined to form a pair. Pairs are created by the following expression.

<u>Expression</u>	<u>Value</u>
$X : Y$	a pair whose head component is X and whose tail component is Y.

The reader should note that the expression $X:Y:Z$ is equivalent to $X:(Y:Z)$ and not to $(X:Y):Z$.

The BALM notation for printing a pair is illustrated below.

```
P=10,20; PRINT(P);  
(10,20)
```

A pair may also be specified as a constant. We again use a quote character, either > or =.

```
P= "10,20"; PRINT(P);  
(10,20)
```

The following expressions may be used with pairs.

<u>Expression</u>	<u>Value</u>
HD P	the head component of P
TL P	the tail component of P
HD P = X	has the value X and the side-effect of changing the head component of P to X
TL P = X	has the value X and the side-effect of changing the tail component of P to X
P1 EQ P2	TRUE if P1 and P2 refer to the same pair,
P1 ≡ P2	NIL otherwise
COPY(P)	described in the section of strings is also very useful with pairs
EQUAL(X1,X2)	described in the previous section is useful in comparing copies of pairs

Since the components of a pair may themselves be pairs we can construct very complex groups of items. An especially useful form of a collection of pairs is called a list.

2.6.1 Pairs and Lists

A list in BALM is an ordered set of items in which the two primitives provided for referring to the components give respectively the first element of the list and the remainder of the list.

Lists can be created by using the operator LIST, which can have an arbitrary number of arguments, and which will give as its value a list with the values of its arguments as elements. A list is constructed out of pairs according to the following definition.

<u>Expression</u>	<u>Value</u>
LIST(X1,X2,...,XN)	X1:(X2: ... (XN:NIL) ...)

For example:

```
ABC = LIST(A+B,12,MAX(V));
```

will create a list whose elements are the value of the expression A+B, the number 12, and the value of MAX(V), and assign this list to ABC. The procedure list is analogous to the operator vector described previously. Of course lists may also be constructed from a given head and a given tail using the colon operator.

For example:

```
ABC = A+B:12:MAX(V):NIL;
```

would have the same effect as the expressions above.

We can think of a list as having two components, a head and a tail which can be referred to by the two primitives, HD and TL. For example, if the value of the variable L is a list of three numbers 1, 2 and 3, then the value of the expression HD L is the number 1, and the value of the expression TL L is the list whose elements are the numbers 2 and 3.

The second element of a list can be referred to as the head of the tail of the list, so HD TL L would be the number 2. Similarly the third element would be referred to as HD TL TL L, and so on. The tail of a one-element list is the empty list which is written as NIL.

A significant property of lists is that in general the tail of a list is also a list. Thus those algorithms which require the elements of a list to be processed in order can be conveniently implemented using an auxiliary variable to keep the unprocessed portion of the list. For example, a piece of program to sum the elements of a list L can be

```
S = 0; R = L;  
WHILE R REPEAT DO S=S+HD R, R=TL R END;
```

Here the variable S is used to accumulate the sum, and the variable R is used to keep the unprocessed part of the list. We are using the fact that the WHILE loop will continue until R is NIL, which denotes the end of the list.

The predicate PAIRQ can be used to test if an arbitrary expression is a non-empty list. For example, we could have written

```
WHILE PAIRQ(R) REPEAT DO S=S+HD R, R=TL R END;
```

in the example given above.

A part of a list can be changed by putting the appropriate reference on the left-hand side of an assignment, as might be expected. However, there is a certain danger in using this facility without care, for the following reason. Lists are represented in memory in such a way that two lists which end in the same elements may use the same portion of memory to store those common elements. This means that any operation which changes an element in one of the lists also changes in an underhand way the element of the other list. This situation can arise in code such as:

```
L = LIST(1,2,3);
X = 4!L; Y = 5!L;
```

At this point the value of X is the list containing the numbers 4, 1, 2, 3 while Y contains 5, 1, 2, 3. If now we executed:

```
HD TL TL X = 9;
```

we would change X to contain 4, 1, 9, 3, but also Y to contain 5, 1, 9, 3. In spite of these warnings, the user can use this facility without problem if he keeps track of which elements are common to which lists.

Lists can be printed by the print routine in a convenient and readable format. This is similar to the format used for vectors, but using parentheses instead of square brackets. Thus the three element list containing the numbers 12, 13, and 14 would be printed:

```
(12 13 14)
```

instead of:

```
(12 13 14,NIL)
```

Similarly this notation can also be used to specify constant lists, if preceded by the quote mark = . Vectors can be elements of lists and vice versa, so we can write things such as:

```
VL = =((12 13) [14 15 16] ([17 18] 19))
```

and so on. Recall that an identifier in such a constant will be treated as a constant, not a variable, and expressions will not be evaluated.

Several useful procedures are available which act upon or result in lists:

LENGTH(L)	returns the number of elements in a list
VFROML(L)	returns a vector whose elements are the same as those of the list given as its argument.
LFRMOV(V)	returns a list whose elements are the same as those of the vector given as its argument.
MEMBER(X,L)	called with two arguments, the second of which must be a list, returns true if the first argument is EQ to one of the elements of the second, For example: if MEMBER(=RED,L) THEN...
SUBST(X,Y,L)	called with 3 arguments, the third of which must be a list. It returns a new list in which argument 1 has replaced argument 2. For example:

```

L=LIST(=RED,=BLUE,=YELLOW,=PURPLE);
NEWL=SURST(=GREEN,=RED,L);
PRINT(L);
(GREEN BLUE YELLOW PURPLE)

```

2.6.2 Examples

Remember that the tail of a one element list is always NIL. In other words NIL marks the end of a list. Thus we can print successive elements of a list in the following way.

```

WHILE L REPEAT DO
  PRINT(HD L),
  L=TL L
END;

```

This will repeat the loop until L is NIL. Suppose L is a list of strings

```
L=LIST(*ONE*,*TWO*,*THREE*,*FOUR*)
```

The first time through the loop

ONE

is printed and the value of L is LIST(*TWO*,*THREE*,*FOUR*). Next

TWO

is printed and the value of L is LIST(*THREE*,*FOUR*). Then

THREE

is printed and the value of L is LIST(*FOUR*). Finally

FOUR

is printed, the value of L is NIL and the loop is terminated.

Suppose we have a list of pairs consisting of an identifier and an integer. A program which will ascertain whether an identifier is on the list and if so print the integer or if not add the identifier and the next highest integer to the list is as follows:

```
LST= (((RED,1) (BLUE,2) (YELLOW,3)))
ID= =GREEN;
BEGIN(PREV,N,L),
L=LST,
WHILE L REPEAT DO
  IF HD HD L EQ ID THEN GO FOUND,
  PREV=L, N=TL HD L, L=TL L
  END,
  TL PREV=(ID;N+1):NIL,
  RETURN N+1,
FOUND, PRINT(ID,TL HD L)
END;
PRINT(L);
```

The first time through the loop HD L will be =(RED.1) thus HD HD L will be =RED.

Note that HD HD L is equivalent to HD(HD L).
TL HD L is l the first time through the loop, and the last time HD HD L is =YELLOW, N is set to 3, PREV is set to LIST(=YELLOW:3) and L becomes NIL. To add the new identifier to the list we need to make the tail of PREV point to a new element. This is done by replacing TL PREV which is NIL with a pointer to a new pair whose head is =(GREEN,4) and whose tail is NIL. The final print of L will result in

```
((RED,1) (BLUE,2) (YELLOW,3) (GREEN,4))
```

EXERCISES

- 2.1 Write a program to test a string and print it if it is palindromic, i.e. ≠MADAM≠.

3.1 A Little About Utility Procedures.

We have already mentioned a number of built-in procedures: PRINT, COPY, EQUAL, etc. A complete list of these predefined or built-in functions exists in Appendix E. All of these are available to the user as part of the BALM system.

All of these procedures are written in BALM and can be found in the BALM system listing in Appendix F either near the front in the section labeled utility procedures or at the end in the section marked supplement. They provide further examples of BALM programs.

In this chapter we will be concerned with user-written procedures. In most cases a BALM program will consist mainly of a number of definitions of user-written procedures, interspersed with one or more commands to invoke these procedures.

3.2 User Defined Procedures and Functions

In general a procedure consists of an expression written in terms of a number of variables, some of which may be designated as standing for arguments. For example, we might want to define a procedure which will take two arguments and return as its value the sum of their squares. The mathematical way of defining this function is something like:

$$F(X,Y) = X \cdot X + Y \cdot Y$$

In BALM we could write this as:

$$\text{SUMSQ} = \text{PROC}(X,Y), X \cdot X + Y \cdot Y \text{ END},$$

Here the expression on the right-hand side of the assignment is a procedure, delimited by the operators PROC and END. Subsequently the procedure can be used in a form such as:

$$A = B * \text{SUMSQ}(C,D+3) - 5,$$

Here the arguments of the procedure are the value of C and the value of the expression D+3. The procedure invocation is evaluated by effectively carrying out the following operations:

1. Save the current values of X and Y
2. Assign the value of C to X and the value of D+3 to Y.
3. Evaluate the expression $X \cdot X + Y \cdot Y$.
4. Restore the original values of X and Y.
5. The value of $\text{SUMSQ}(C,D+3)$ is given by step 3.

The reason for steps 1 and 4 is that it is desirable to be able to define a procedure so that any changes made to the values of the variables used to indicate its arguments will not affect the values which they may have elsewhere.

The expression used to define a procedure can be one of considerable complexity, including a block. The procedure mentioned in a previous section which calculates $1*2*3\dots*N$ for an argument N, could be defined:

```
FACT = PROC(N),
      BEGIN(I,NN),
      NN=1, I=1,
      NXT, IF I GT N THEN RETURN NN,
      NN=NN*I,
      I=I+1,GOTO NXT
END END;
```

and could then subsequently be applied like any other procedure.

Thus **PRINT (FACT(5))**

would print out the value 120.

Below are some expressions which are useful when writing procedures.

<u>Expression</u>	<u>Value</u>
NUMARGS()	returns the number of arguments of the current procedure
ARGUMENT(I)	returns the Ith argument of the current procedure

These make it possible to call a procedure with a variable number of arguments. For example

```
PRTARGS=PROC(),
BEGIN(N,I),
N=NUMARGS(),
FOR I=(1,N) REPEAT
PRINT(ARGUMENT(I))
END END;
PRTARGS(10,20,30);
```

would print

```
10
20
30
```

and

```
PRTARGS(*STRING*)
```

would print

```
*STRING*
```

Note: Procedure PRTARGS must be defined before it is executed.

In BALM all procedures are functions. That is they all have values. The value of a procedure is the value of its expression. Normally a procedure consists of a block or a compound expression but it may as in the case of SUMSQ in the example above be a simple expression.

Procedures may also have side effects such as modifying a variable or modifying a data structure pointed to by an argument. Procedures may not, however, return data to the calling program by modifying values of variables given as arguments since only the values of the arguments are transmitted to the procedure. We shall discuss this in more detail in Section 3.3.

We need not call a procedure directly in BALM but may use APPLY.

<u>Expression</u>	<u>Value</u>
APPLY(C,X)	returns the value of procedure C where applied to argument X. If X is a list it is considered to be a list of arguments and C will be applied to the members of the list. If X is not a list it is considered to be the sole argument of C.

Suppose we want to write a function of two arguments defined as follows. If argument 1 is an integer then the function should return that element of the vector specified by argument 2. If the 1st argument is code then it should return the result of executing the procedure with the arguments which are members of the list specified by the 2nd argument.

```
OF=PROC(F,Y),
  IF INTQ(F) THEN Y[F]
  ELSEIF CODEQ(F) THEN APPLY(F,Y)
  ELSE NIL
  END;
V=={10 20 30};
PRINT(OF(3,V))
```

would print

30

and

would print

20

3.3 Name Scoping

So far we have not really dealt with the problem of name scoping or what it means to make a variable local to a block. It is important to make variables local to blocks within procedures to prevent unwanted side effects. Perhaps an example will serve to illustrate the seriousness of the problem.

Suppose we wish to determine how many elements of a list and a vector are the same. Suppose we know that those elements are themselves vectors and we write a procedure named SAMEV to return TRUE when its arguments are the same, NIL otherwise.

```
SAMEV=PROC(X,Y),
BEGIN(),
  IF SIZE X NE SIZE Y THEN RETURN NIL,
  IF NOT VECTQ(X) OR NOT VECTQ(Y) THEN RETURN NIL,
  FOR I=(1, SIZE X) REPEAT
    IF X[I] NE Y[I] THEN RETURN NIL,
    TRUE
  END END;

V= {[1 2] [2 3] [1 3]};
L= {[1 3] [2 3] [1 2]};
N=0;
I=1;
WHILE L REPEAT DO
  IF SAMEV(HD L, V[I]) THEN N=N+1,
  I=I+1, L=TL L
END;

PRINT(N,=MEMBERS,=ARE,=SAME);
```

Note that the procedure must be defined before it is executed.

We can see that element 2 is the same and is in the same position in both the list and the vector. Therefore, we would expect the print to have the following effect.

```
1 MEMBERS ARE SAME
```

However, SAMEV uses I and I is not local to its block. When SAMEV is called I has the value 1 but upon exit from SAMEV I has a value of 2 so the statement I=I+1 will set I to 3. The second time through the loop, element 2 of the list will be compared to element 3 of the vector. The third time through the loop element 3 of the list will be compared to element 2 of the vector. The answer is

```
0 MEMBERS ARE SAME
```

This example illustrates the need for local variables. Procedure SAMEV should not be modifying I in the calling program. I can be made local to SAMEV by inserting it in the list following BEGIN.

```
BEGIN(I),
```

While the rules for name scoping in BALM are simple and straightforward they may seem confusing to users with experience in some other programming languages. In most programming languages storage allocation and, therefore, name scoping is determined at compile time and remains static during execution. In BALM name scoping is dynamic, that is the meaning of variables is determined during execution rather than procedure definition.

A name used in a BALM expression normally refers to a variable. Corresponding to each name is a unique identifier. Any occurrence of the name refers to the current value of that identifier.

A variable is made local to a block by appearing in the declaration following a begin. For example:

```
; BEGIN (A,B,C)
```

makes A, B, and C local to the block. On entry to the block the current value of each local identifier is saved. On exit from the block that value is restored. Therefore any use of an identifier between entering and leaving a block to which it is declared local will not change the value it had prior to entering the block. As a general rule it is good practice to declare all variables to be local whose values are not needed outside a block. The user should be particularly careful to declare as local all index variables used in FOR loops. They are frequently forgotten and are rarely needed outside the block.

A variable used in a block in which it is not declared local is called global (to that block). Such variables can be used to transmit parameters to the block or procedure, and any changes made to their values within the block will have effect outside the block. Note that a variable can be local to block or procedure A, but be global to a block or procedure invoked between entering and leaving A. This is often convenient when writing a package of procedures whose subprocedures have many arguments or always the same arguments. For example

```

OUTLINE= PROC(),
BEGIN(ITM),
  ITM=READ(INPUT),
  IF EOF(ITM) THEN RETURN NIL,
  IF PAIRO(ITM) THEN MLIST()
  ELSEIF VECTQ(ITM) THEN MVECT()
  .
  .
  ELSE PRINT(*ERROR ON INPUT FILE*)
END END;
MLIST= PROC(),
DO PRINT(=LIST,ITM),
  .
  .
END END;

```

The variable ITM is declared local to procedure OUTLINE and thus has no effect on any procedure entered before OUTLINE is invoked. The variable ITM is however, global to procedure MLIST, MVEC, etc. and to any procedure called by OUTLINE where it is not specifically declared to be local.

Similarly on entry to a procedure the current values of the identifiers named as arguments are saved. The actual value of the argument then replaces the value of the identifier. The original value is restored upon exit from the procedure.

3.4 Recursive Procedures

In an earlier section we gave the code to sum the elements of a list. This can be written as a procedure in the following way.

```

LSUM = PROC(L), BEGIN(S,R),
  S = 0, R = L,
  WHILE R REPEAT DO S=S+HD R, R=TL R END,
  RETURN S   END END;

```

An alternative way of writing this procedure makes use of the fact that we can say that the sum of a non-empty list is the sum of the head and the sum of the tail of the list. That is, when the list is not empty, we can say

$$LSUM(L) = HD\ L + LSUM(TL\ L)$$

Putting in the test for an empty list, whose sum is zero, we get the following concise definition:

```

LSUM = PROC(L),
  IF L EQ NIL THEN 0 ELSE HD L + LSUM(TL L)
END;

```

This type of definition, called a recursive definition, is quite often convenient for operations on lists. In the simple case given here, a non-recursive definition is also simple, but in more complex cases recursion permits the complexity of an algorithm to be significantly reduced, so the reader should make himself familiar with the technique.

As a simple example, suppose we write a procedure to append two lists, that is, to construct a list whose elements include those of both arguments. At first sight this is a little tricky, since we have to add the last element of the first list to the beginning of the second list, then the second to last, and so on. However, the following recursive implementation accomplishes this:

```
APPEND = PROC(X,Y),
    IF X=NIL THEN Y ELSE HD X:APPEND(TL X,Y)
    END;
```

This is another example of the usefulness of recursion. A non-recursive implementation is more complicated, but can be written as follows:

```
APPEND = PROC(X,Y), REVAPP(REVAPP(X,NIL),Y) END,
REVAPP = PROC(L,R),
BEGIN(),
MOR, IF L EQ NIL THEN RETURN R,
R = HD L;R, L = TL L, GO MOR
END END;
```

Here we have used an auxiliary routine REVAPP which is similar to APPEND, but reverses its first argument. Thus the value of REVAPP(X,NIL) is simply a list whose elements are the same as those of X, but in the reverse order. REVAPPING this onto the list Y will then give the required result.

Example: TOWER OF HANOI

Tower of Hanoi is a game which consists of three spindles and some rings of different sizes. The rings are to be moved from one spindle to another without violating the following rules.

- (1) only one ring may be moved at a time.
- (2) a ring may be moved from any spindle to any other.
- (3) at no time may a larger ring rest upon a smaller ring.

The following recursive function prints the steps necessary to move N rings from one spindle to another.

```
HANOI=PROC(N,ST,DEST,INTERM),  
IF ZR N THEN NIL ELSE DO  
    HANOI(N-1,ST,INTERM,DEST),  
    PRINT(=MOVE,=RING,N,=FROM,ST,=TO,DEST),  
    HANOI(N-1,INTERM,DEST,ST)  
END  
END;
```

```
HANOI(5,=A,=C,=B);  
MOVE RING 1 FROM A TO C  
MOVE RING 2 FROM A TO B  
MOVE RING 1 FROM C TO B  
MOVE RING 3 FROM A TO C  
MOVE RING 1 FROM B TO A  
MOVE RING 2 FROM B TO C  
MOVE RING 1 FROM A TO C  
MOVE RING 4 FROM A TO B  
MOVE RING 1 FROM C TO B  
MOVE RING 2 FROM C TO A  
MOVE RING 1 FROM B TO A  
MOVE RING 3 FROM C TO B  
MOVE RING 1 FROM A TO C  
MOVE RING 2 FROM A TO B  
MOVE RING 1 FROM C TO B  
MOVE RING 5 FROM A TO C  
MOVE RING 1 FROM B TO A  
MOVE RING 2 FROM B TO C  
MOVE RING 1 FROM A TO C  
MOVE RING 3 FROM B TO A  
MOVE RING 1 FROM C TO B  
MOVE RING 2 FROM C TO A  
MOVE RING 1 FROM B TO A  
MOVE RING 4 FROM B TO C  
MOVE RING 1 FROM A TO C  
MOVE RING 2 FROM A TO B  
MOVE RING 1 FROM C TO B  
MOVE RING 3 FROM A TO C  
MOVE RING 1 FROM B TO A  
MOVE RING 2 FROM B TO C  
MOVE RING 1 FROM A TO C
```

The program logic can be seen by induction. Clearly, moving zero rings requires no steps. Moving one ring requires one step.

MOVE RING 1 FROM A TO C

Moving two rings requires three steps.

MOVE RING 1 FROM A TO B
MOVE RING 2 FROM A TO C
MOVE RING 1 FROM B TO C

The general solution is:

- (1) move N-1 rings from A to B
- (2) move ring N from A to C
- (3) move N-1 rings from B to C

In procedure HANOI the arguments are as follows:

- (1) N - the number of rings to move
- (2) ST - the starting spindle
- (3) DEST- the destination spindle
- (4) INTERM-the intermediate spindle

The logic follows the general solution. If N is zero then the function is done and returns NIL. Otherwise HANOI is called recursively to move N-1 rings from the starting spindle to the intermediate spindle. When that is done, the print statement directing the user to move disc N from start to destination is executed. Finally, HANOI is called recursively to move N-1 rings from intermediate to destination.

EXERCISES

- 3.1 A tree is constructed out of pairs and integers.
Write a BALM procedure COUNT which will return as its value the number of integers in the tree given as its argument.
- 3.2 Write a procedure EQLVQ(L,V) which will have the value TRUE if the list L and the vector V contain the same elements in the same order. Assume the elements are integers.
- 3.3 One representation of a set in BALM is as a list whose elements are the elements of the set. Assuming that the elements are either sets or integers, write a procedure EQSETQ(X,Y) which will return TRUE if sets X and Y contain the same elements.

CHAPTER 4. INPUT/OUTPUT.

4.1 Printing and Reading

BALM has two predefined files

INPUT and OUTPUT

and several predefined utility procedures for doing I/O. Other files and other I/O procedures may be specified by the user. We will discuss how to do this in the next section.

The simplest output operation uses the standard procedure PRINT:

PRINT(X1,X2,X3, ... ,XN)

X1 through XN are written on the file which is the value of OUTPUT. The value of PRINT is XN. PRINT may output more than one line. An output line is defined as having 73 characters. The first character is used for carriage control

Printing conventions for BALM items are as follows:

INTEGERS

10 08 778

Note, if a user wishes numbers printed as octal he must set a switch
OCTMODE=TRUE;

The default is for integers to be decimal

OCTMODE=NIL;

LABELS

/3/ /10/ /9/

Labels are assigned a unique number within their block by the BALM compiler. They are printed with slashes to avoid confusion with integers.

LOGICALS

TRUE NIL

IDENTIFIERS

ABC P1234 ALONGNAM

CODE

/PROC TEST/ /PROC SUMSQ/

Code is printed with the name which appeared on the left-hand side of the equal sign when the procedure was defined.

STRINGS

#A LONG STRING# #NUMBERS 1-2-3#

Strings are enclosed in quotes for printing.

VECTORS

```
[A B CD] [[1 2] [1 3] [1 4]]
```

Vectors are enclosed in square brackets. The print program keeps track of how many levels of nesting have occurred. It puts as much as possible on a single line but each time it starts a new line it indents one space for each level of nesting.

```
(ONLY ONE LEVEL OF NESTING OCCURS  
HERE)  
([TWO LEVELS OF NESTING OCCUR  
HERE])  
(ONLY ONE [LEVEL OF NESTING]  
OCCURS HERE)
```

If there are more than 20 levels the print program starts over at the left margin.

PAIRS

```
(A . B) (X Y Z) (W X Y , Z)
```

Pairs are printed as

```
(1 . 2)
```

except when the tail is

(1) another pair

1:2:3:4 prints as (1 2 3 . 4)

(2) NIL

1:NIL prints as (1)

1:2:3:4:NIL prints as (1 2 3 4)

The same indenting rules described with vectors are used to indicate levels of nesting of pairs.

```
(THERE IS ONLY ONE LEVEL OF  
NESTING HERE)  
(THIS IS AN EXAMPLE OF (TWO  
LEVELS OF NESTING))
```

A correct program should never produce anything but BALM data-objects. However, a program with a bug in it could conceivably produce a value which is not a valid BALM item. In this PRINT prints

This is an indication of a program bug; a correct program should never produce anything but BALM data-objects.

Frequently a user wishes to write a program which reads its data from an input file. This allows the user to vary the data without modifying the program.

The BALM system has several input functions for this purpose. The simplest is READ. READ has one argument which is a file name. We shall see in the next section how to create files, but if the user wishes to read from the input he uses the predefined variable INPUT.

```
X=READ(INPUT);
```

The value of READ is the next BALM data-object on the file. The same conventions used in printing BALM items apply to reading.

Thus if

```
(1 2 3)
```

is on the input file and READ(INPUT) is executed then its value is the list whose members are 1, 2 and 3.

Since execution in BALM takes place as soon as the system encounters a semicolon, data must be interspersed with BALM programs. In the following examples, we shall follow the convention of prefacing lines input by the user with => . For example

```
=> DO A=READ(INPUT), B=READ(INPUT), C=READ(INPUT) END;
=> (A B C) [X Y Z] 10B
=> PRINT(A);
(A B C)
=> PRINT(B);
[X Y Z]
=> PRINT(C);
8
=> OCTMODE=TRUE;
=> PRINT(C);
10B
```

READ recognizes strings, lists, identifiers, vectors, and integers, but not labels or code. Thus, it is not possible to read labels or code.

Non-alphanumeric characters such as , * = + - ; which do not have any special meaning in representing BALM items are treated as one character identifiers by READ. For example:

```
=> DO X=READ(INPUT), Y=READ(INPUT), Z=READ(INPUT) END;
=> A , B
=> PRINT(X);
A
=> PRINT(Y);
'
=> PRINT(Z);
R
```

Spaces are ignored by READ except when they serve as separators between names or numbers.

4.2 Defining Other Files

Since I/O is the most implementation dependent part of the BALM system we shall assume the user has a CDC 6600 but we shall note those functions which are general and are applicable to other implementations.

Before a file can be read it must be defined using the BALM function MAKFILE.

MAKFILE(FN,!)

returns a vector which contains information about the file necessary for reading and writing. The first argument is the file name and the second argument is the line length. The file name is an integer N meaning TAPEN in the FORTRAN sense.

For example:

```
MYFILE=MAKFILE(4,72);
X=READ(MYFILE);
```

defines MYFILE as being TAPE4 and causes X to be set to the first item on that file. Alternatively on the 6600, the file name may be specified as a string.

```
NEWF=MAKFILE(#FILZZ#,80);
Z=READ(NEWF);
```

NEWF is defined as being the local file named FILZZ with a line length of 80. The value of Z is the first item on that file.

On the 6600 buffer space for files can be reused when the file is no longer needed. The BALM system is informed that a program no longer needs a file by use of the CLOSE operation.

CLOSE(FN)

FN may be either a string containing the file name or an integer. CLOSE puts an end of file on the file if the last operation was a WRITE. Buffers are released and may be used for another file.

Example: CLOSE(4);

closes the file known as TAPE4.

```
CLOSE(#FILZZ#);
```

closes the file known as FILZZ.

4.3 Other I/O Functions

```
WRITE(X,FIL);
```

X is written on file FIL. The value of WRITE is X. Write uses the same conventions as PRINT but the item is written on the file which is its second argument. Another difference is that WRITE is always called with 2 arguments while PRINT accepts a variable number. Example:

```
OUTF=MAKFILE(*PUNCH*,72);
DATA=# THIS IS AN OUTPUT MESSAGE#;
WRITE(DATA,OUTF);
```

These expressions define OUTF as being the local file PUNCH, and write the string #THIS IS AN OUTPUT MESSAGE# on that file. On the 6600 this would result in one card being punched.

```
RDTOKEN(FIL)
```

RDTOKEN is quite similar to READ but slightly more primitive. RDTOKEN behaves in the same way as READ for integers, identifiers and strings, but doesn't construct lists or vectors. If it encounters a parenthesis, bracket, or period it returns an identifier whose name is a parenthesis, bracket, or period respectively. In the following example lines input by the user are prefaced by =>. For example:

```
=> DO A=RDTOKEN(INPUT), B=RDTOKEN(INPUT), C=RDTOKEN(INPUT) END+
=> ( 1 , 2 )
=> PRINT(A);
(
=> PRINT(B);
1
=> PRINT(C);
```

The parentheses and brackets are returned as one character identifiers. For example:

```
BEGIN(),
A=RDTOKEN(INPUT),
IF A EQ IDFROMS(()) THEN MAKLIST()
ELSEIF A EQ IDFROMS(()) THEN MAKVECT()
ELSEIF A EQ *. THEN MAKD()
.
.
.
END;
```

Note that the expression IDFROMS must be used to create an identifier from parentheses or brackets. This is to avoid confusion with the notation for constant lists and vectors.

EOF(X)

EOF is a function which returns TRUE if its argument is an end of file, NIL otherwise. It is used in conjunction with READ or RDTOKEN. For example:

```
BEGIN(ITM),
NEWF=MAKFILE(3,89),
RD,ITM=READ(NEWF),
IF EOF(ITM) THEN GO FIN
ELSE
'
'
'
GO RD,
FIN,PRINT(*PROCESSING COMPLETE*)
END;
```

SAVEBALM(FN)

SAVEBALM is a procedure which provides a facility quite different from the other read and write routines. It allows the user to write a copy of the current machine state to a file. This file can subsequently be used to resume execution at a different time.

Suppose that you have written a very useful BALM procedure which several people would like to use. You might copy your BALM source program and give them each a deck of cards to place in front of their BALM programs. But, if your program is very long then may be spending most of their computer time recompiling. It would be more efficient for you to compile it and then create a saved file which they can use when they wish to call your procedure.

```
MYPROC=PROC(A,B,C),
BEGIN(),
'
'
END;
```

SAVEBALM(#OWNSFIL#); A local file known as #OWNSFIL# is written and contains the state of the machine, that is all variables, registers, procedures, etc. This file can only be read by the RESUMEAL operation.

RESUMEAL(FN)

reads the machine state from file FN and resumes execution.

```
RESUMEALL(#OWNSFIL#);
MYPROC(10,20,30);
```

Suppose that #OWNSFIL# is the one created by SAVEBALM above. Once the RESUMEALL has been executed MYPROC is defined and can be used. In Chapter 6 we shall discuss how to effect automatic resumption from a saved file.

There are also several more primitive I/O operations which can be used to construct read and write procedures in case the predefined procedures do not suit a user's needs.

Expression

Value

RDLINE(FN)

a string which represents the next line of the file with trailing blanks deleted. All blanks are represented by a string of length 1 consisting of # #. When an end of file is read a string of length 0 is returned.

If the user wishes to use RDLINE with the input file he may use the integer 1 as it is synonymous with the input file.

Example:

```
S=RDLINE(1);
ABCDEFGHIJKLMNOPQRSTUVWXYZ
PRINT(S);
*ABCDEFGHIJKLMNOPQRSTUVWXYZ*
```

OPEN(FN,I)

value is the first argument. The first argument gives the file name and may be either an integer or string. Argument 2 gives the line length. If a file is read without first executing OPEN then the line length is assumed to be 72.

Example:

```
OPEN(#MYFILE#,90);
Z=RDLINE(#MYFILE#);
```

WRLINE(S,FN)

the string S is written on file FN and S is returned.

The integer 2 is synonymous with the output file and should be used with WRLINE on output. Example:

```
WRLINE(# THIS IS AN OUTPUT MESSAGE#,2);
THIS IS AN OUTPUT MESSAGE
```

<u>Expression</u> (Cont'd).	<u>Value</u>
ENDFILE(FN)	FN is returned and an end of file is written on the designated file.
REWIND(FN)	FN is returned and the designated file is rewound.
BACKSPACE(FN)	FN is returned and the designated file is backspaced.
SAVEALL(FN)	FN is returned and the machine state is written on the designated file.

Note: the procedure SAVEBALM uses the operation SAVEALL.

CHAPTER 5. SUMMARY

We have covered now most of the features of the BALM language. Chapter 1 detailed how to combine operators to construct expressions:

programs:
A = 10+20/5

conditional expressions:
A=10;
PRINT(A);

IF X THEN Y ELSE Z
IF X THEN Y
IF X THEN Y ELSEIF A THEN B ELSE Z

loops:
WHILE P REPEAT C
FOR V=(I1,I2,I3) REPEAT C

compound expressions:
DO C1, C2, C3, ... CN END

and blocks:
BEGIN(V1,V2, ... VN),
X1, X2, ... XM
END

We also learned that labels and gotos and returns are associated with blocks.

Chapter 2 describes BALM items

logical
integer
label
pointer-to-identifier
pointer-to-code
pointer-to-string
pointer-to-pair
pointer-to-vector

All the primitive operations available to construct expressions involving BALM items are listed in Chapter 2.

Of particular note are the problems inherent in assignment and the necessity for copying when items are pointers. The built-in procedures COPY(X) and EQUAL(X1,X2) provide copying capability and the ability to determine if items point to equivalent objects.

How to define a procedure is described in Chapter 3.

PROCNAME= PROC(ARG1,ARG2, ... ARGN), X END

A procedure can contain only one expression although that expression may be a block or compound. Procedures can be written to accept a variable number of arguments by using
NUMARGS()

which returns the number of arguments and

ARGUMENT(I)

which returns the I-th argument.

Name scoping is dynamic in BALM, that is, the meaning of a variable is determined at execution time, not compile time. All variables are global unless specifically declared local by appearing in a BEGIN list. Local means that a variable is known in the block where it is defined and in all blocks entered from that block. Likewise procedure arguments are known in the procedure where they are defined and in all procedures called from that procedure. The calling program does not receive a new value assigned to an argument by a procedure. Procedures can pass information to a calling program as a function or by modifying a string, list, or vector pointed to by an argument.

Print conventions discussed in Chapter 4 are as follows

integers	10 1018 89
logicals	TRUE NIL
labels	/10/ /3/ /2/
identifiers	ABC HELLO P12345
code	/PROC TEST/ PROC FACT/
string	*A STRING* *1234 /// 10*
vector	{1 2 3} [X YY Z]
pair	(10 , 20) (10) (10 20 30)

Input data should be in the same format as printed data.

Procedure READ constructs the appropriate BALM item.

5.1 COMMENT

We have already noted that any line with a star in column 1 is treated as a comment. There exists a further mechanism for placing comments on a line or imbedding them in code.

COMMENT x no value. comments are ignored. x may be any BALM constant: list, string, vector, identifier or integer, but a string is the usual choice.

COMMENT may follow any infix operator, but usually follows a comma. The program should be syntactically correct when COMMENT x is removed, so a comma should not be found both before and after the comment. Example.

```
* A PROGRAM TO DEMONSTRATE BALM
* INPUT AND OUTPUT
DEMO = PROC(),
BEGIN(ITM),
ST, ITM = READ(INPUT),
IF EOF(ITM) THEN GO DONE,
IF INTQ(ITM) THEN PRINT(=TYPE,=INTEGER,ITM)
ELSEIF LOGQ(ITM) THEN PRINT(=TYPE,=LOGICAL,ITM)
'
ELSE PRINT(=UNKNOWN,=TYPE), COMMENT *ALL TYPES TESTED*
GOTO ST,
DONE, PRINT(*END OF FILE ON INPUT*)
END
END;
```

CHAPTER 6. RUNNING A BALM PROGRAM

6.1 Source Input

The control card to direct the system to execute BALM4 on the CDC 6600 is

BALM4,

or

BALM4(INPUT,OUTPUT)

These two cards have exactly the same effect. Input and output are the default files. BALM4 expects to find the BALM source program on file INPUT. It places its output on file OUTPUT.

If the source program is on local file BINP then

BALM4(BINP)

or

BALM4(BINP,OUTPUT)

tells BALM4 that BINP is the file containing the source program.

If the user desires the output from BALM programs to go to the local file BOUT then

BALM4(,BOUT)

or

BALM4(INPUT,BOUT)

are appropriate cards. Finally

BALM4(BINP,BOUT)

directs BALM4 to read from BINP and write on BOUT.

6.2 Deck Setup

Two files are necessary to run a BALM program. One is a saved file which can be created by procedure SAVEBALM described in Chapter 4. The other is a program which simulates an MBALM machine on the target machine, in our case a CDC 6600. See Appendix B for details about other target machines. Chapter 10 describes the MBALM machine and its part in the BALM system implementation.

The program which simulates the MBALM machine on the CDC 6600 expects to find the saved file on local file BLM4SVD. There are two versions available on the 6600. One version requires a field length of about 60000 octal and is suitable for short programs. The control cards to run this version are

```
X123456,CM60000. USER NAME  
ATTACH(BALM4,BLM4SVD)  
BALM4,  
GREEN END OF RECORD CARD  
  
' BALM SOURCE PROGRAM  
  
' PINK END OF FILE CARD
```

The other version translates MBALM code directly into machine language. It runs between 6 and 10 times faster than the previously described version. It requires a field length of about 120000 octal and is more suitable for long programs. It can be run with the following control cards.

```
X123456,CM120000. USER NAME  
ATTACH(TBALM4,BLM4SVD,TBLM4SVD)  
TBALM4.  
GREEN END OF RECORD CARD  
  
' BALM SOURCE PROGRAM  
  
' PINK END OF FILE CARD
```

The following deck setup gives an example of a program which reads cards from a file other than input.

```
X123456,CM60000. USER NAME  
ATTACH(BALM4,BLM4SVD)  
COPYBK(INPUT,INFIL)  
REWIND(INFIL)  
BALM4,  
GREEN END OF RECORD CARD  
  
' DATA CARDS  
  
' GREEN END OF RECORD CARD  
  
' INP=MAKFILE(*INFIL*,80);  
  
' ITM=READ(INP);  
  
' PINK END OF FILE CARD
```

If a user wishes to automatically resume execution from a saved file which he created in an earlier run that file must be local file BLM4SVD.

```
X12330456,CM60000. * USER NAME *
ATTACH(BALM4,BLM4SVD=OWNSAVEDFILE)
BALM4,
```

or

```
X123456,CM120000, USER NAME
ATTACH(BALM4=TBALM4,BLM4SVD,OWNTSAVEDFILE)
BALM4,
```

Note: A saved file must be used with the same version of BALM4 with which it was created.

INTERCOM OPERATION

BALM may be run interactively using the CDC INTERCOM time-sharing system. The following commands are necessary to execute BALM programs. The system messages are in lower case, the user responses in upper case.

```
LOGIN,
'
'
command• ATTACH(BALM4,BLM4SVD)
command• EFL(60000)
command• CONNECT(INPUT)
command• BALM4.
```

In batch operation the BALM compiler echos each line of input on the output file. This can be inhibited on the teletype by setting

```
TTYFLAG=TRUE;
```

The system subsequently prints a > each time it is ready to read a line of input.

```
TTYFLAG=TRUE;
TTYFLAG=TRUE;
>PRINT(*HI*)
*HI*
```

>

The user may issue commands to the SCOPE operating system by prefacing the line with an exclamation point.

```
>PRINT(*TESTING*);  
*TESTING*  
  
>+ETL(100)  
>PRINT(*HELLO*);  
*HELLO*
```

The INTERCOM user is normally advised to enter a semicolon as soon as an error message is received since complete compilation will not be attempted after an error. He may then start typing his program again from the previous semicolon.

For example,

```
>BEGIN(I),  
>WHILE I LT 10 I=I+1  
*** (I IS NOT AN OPERATOR) ***  
>;  
(1 ERRORS)
```

>

There is an editor available for the intercom user which permits the user to make corrections without retying everything since the last semicolon. It is available on request and is not part of the normal BALM system. It is described in BALM Bulletin No. 12.

6.3 Compilation Errors and Messages

The name of the BALM procedure which produced the error message is listed following the message. If the explanation is unclear the user may consult the BALM system listing in Appendix F.

(ASSIGN ERROR)

ASSIGN,

caused by placing a constant on the left-hand side of
an equal sign.

10=A+B

(BRACKETS DONT MATCH)

GETV,

A constant vector has a missing right bracket,
ABC= =[10 20 [1 2];

*** (N COMPILE ERRORS IN ---) ***

CODEGEN,

The number of errors produced by the code generator for
the procedure whose name appears in the message.

No code is generated

(N ERRORS)

EXECUTE

The number of syntax errors in the current program.
No code is generated.

*** (ERROR IN OCTAL NUMBER) ***

LXSCAN,

An octal number with an 8 or 9 appears in the text,
1019B

*** (EXPECT ELSE HAVE ---) ***

GELSE

A conditional statement is illformed.

*** (FOR ERROR) ***

GFOR

A FOR loop is ill formed.

FOR I=1,10 REPEAT ...

*** (IMPROPER USE OF ---) ***

ANALYSE,

A syntax error has occurred, caused by using a predefined
infix operator incorrectly.

A=B+*X;

*** (--- IS NOT AN OPERATOR) ***

OPERROR, (called from ANALYZE)

A syntax error has occurred, caused when the parser
expects to find an infix operator and does not.

WHILE A EQ B PRINT(FAZ);

*** (INPUT INVALID NO CODE COMPILED) ***
SUBLELS,

A syntax tree of incorrect format has been passed to the code generator or one of the generator routines created incorrect results, probably the result of user extensions.

*** (MISSING END AFTER BEGIN) ***
GPROG

*** (MISSING END AFTER DO) ***
GPROGN

*** (MISSING END AFTER PROC) ***
GLAMBDA

*** (MISSING OPERAND BEFORE -) ***
ANALYSE,

The - in the message is a) or a] or a ; . This is a syntax error caused by improper use of a built-in operator.

*** (MISSING --) ***
ANALYSE,

The -- in the message is either a) or a]. Syntax error caused by omitting a closing) or].
A[I = 10;

*** (--- NOT VALID LHS) ***
GSETC

An expression appeared on the left-hand side of an equal sign.

A(I)=10;

*** (---- NOT VALID THEN CLAUSE) ***
GELSE

Probably caused by an unparenthesized nested IF clause:
IF cond THEN IF cond1 THEN expr1 ELSE expr2 ELSE expr;
Add parentheses around the inner if; correct form is
IF cond THEN(IF cond1 THEN expr1 ELSE expr2) ELSE expr;

(PARENS DONT MATCH)

GETLIST,

A constant list is defined with missing parentheses,
L= =(10 A C;

*** (WARNING ----- GREATER 8 CHARACTERS) ***
LXSCAN,

This is only a warning and can be ignored. Since BALM only accepts 8 character names anything else is truncated. This message serves to remind the user that BALM is seeing only 8 characters.

*** (WHILE ERROR) ***

GWHILE

A while loop is ill formed.
WHILE C LT 10 THEN PRINT(C);

6.4 Run Time Errors and Messages

**** ATTEMPT TO APPLY A NON PROC IN -----

The procedure named in the message contains an expression of the form

APPLY(F,L)

and F is not a BALM item of type code; possibly F had syntax errors and no code was generated. Also recall that a procedure must be defined before it can be executed.

*** ATTEMPT TO GOTO A NON LABEL IN PROCEDURE -----

The procedure named in the message contains an expression of the form

GOTO L

where L is not a BALM item of type LABEL, possibly the definition of L occurs within a compound, loop or conditional.

For example

BEGIN(), ... DO L, ..., END END;

BLOCK BOUNDS ERROR

Might be caused if there is no way to exit from the block.

Another possibility is a reference to a label outside the block.

*** ----- CALLS A NON PROCEDURE

The procedure named in the message contains an expression of the form

F(X)

where F is not a BALM item of type code. Possibly caused by syntax errors in F so that no code was generated. F must be defined before it can be executed.

DATA STRUCTURE EXCEEDS GARBAGE COLLECTOR STACK

The garbage collector is unable to trace a data structure. This is most likely the result of trying to use a BALM primitive with an item of incorrect type. For example

HD NIL = Y

ERROR NOT A PROCEDURE - PROGRAM ABORTED

The error recovery procedure (described in 7.1) has been redefined as an item whose type is not code.

GARBAGE COLLECTION CAN RECOVER LESS 1/20 HEAP SPACE EXECUTION TERMINATED

The garbage collector cannot recover enough space to continue executing. The user should verify that his program is not in a loop and then increase the field length. The statistics at the end indicate the maximum height of the stack. A height greater than 4000 may be an indication of infinite recursion. Infinite recursion can be caused by attempting to copy or print a structure which points to itself.

GARBAGE COLLECTOR FOUND AN INVALID TYPE
SYMBOL TABLE ENTRY ---
NAME -----

This is probably the result of attempting to use a BALM primitive with an item of incorrect type. For example

HD VECT = LIST1()

GARBAGE COLLECTOR FOUND AN INVALID TYPE
SYMBOL TYPE STRING ENTRY ---
NAME -----

Probably the result of attempting to use a BALM primitive with an item of incorrect type.

GARBAGE COLLECTOR FOUND AN INVALID TYPE
STACK ENTRY -----

Probably the result of attempting to use a BALM primitive with an item of incorrect type.

GARBAGE COLLECTOR FOUND AN INVALID POINTER
SYMBOL TABLE ENTRY ---
NAME -----

Probably the result of attempting to use a BALM primitive with an item of incorrect type.

GARBAGE COLLECTOR FOUND AN INVALID POINTER
SYMBOL TYPE STRING ENTRY
NAME ---

Probably the result of attempting to use a BALM primitive with an item of incorrect type. For example attempting to take the HD of a vector.

GARBAGE COLLECTOR FOUND AN INVALID POINTER
STACK ENTRY -----

Probably the result of attempting to use a BALM primitive with an item of incorrect type. For example attempting to index a list.

INCOMPLETE TRANSLATION

INSUFFICIENT SPACE FOR BALM EXECUTION

Increase the field length on the job card.

INVALID ARGUMENT TO I/O FUNCTION

Primitives RDLINE, WRFILE, REWIND, ENDFILE, BACKSPACE, SAVEALL. RESUMEAL must be called with a string or integer indicating the local file name.

INVALID DATA ON RESTORE FILE

Either the local file known as BLM4SVD at start of execution is not a BALM saved file or is incompatible with the current system, or the user's program contains an expression of the form

RESUMEAL(FN)

where FN does not contain a saved file. In the second case the user should be sure his file has been rewound.

*** ---- IS NOT A PROCEDURE

One of the user's programs contains an expression of the form
-----(X)

The value of the variable named in the message is not of type code.
It may have had syntax errors when defined so that code
was not generated or it has not yet been defined.
In the case where the user receives the message

*** , IS NOT A PROCEDURE

he has probably used an illformed expression not detected
by the parser. For example

F=PROC(X,Y), X1, X2 END;

MORE THAN -- CALLS TO ERROR = PROGRAM ABORTED

The current default allows for 10 errors. After that
execution is terminated.

NOT ENOUGH SPACE FOR NEW FILE -----

Either there is not enough space to allocate buffers or the
user has too many files open at the same time. Closing unused
files should solve the problem.

NOT ENOUGH SPACE NEED -- MORE WORDS

The garbage collector was able to recover at least 1/20 of the
total space available for data. However, a request was made
for more than the space now available. If this is not the
result of a program bug, the user can increase the field length.

STACK HEIGHT MISMATCH

SUBSTRING ERROR -- RESULT TRUNCATED IN PROC -----

UNDEFINED MBALM --

An attempt was made to use an MBALM opcode which does not
have an instruction associated with it. Probably a system
error, although could be caused by using a saved file recently
created with an old simulator.

The user's job may be aborted with one of the following
scope error messages.

ADDRESS OUT OF RANGE OR ARITHMETIC ERROR

This is probably the result of using a primitive operation or
procedure with a BALM item of inappropriate type. For example

CONCAT(PAIR1,PAIR2); OR HD VECTOR1 OR TL NIL=1

6.5 Storage Allocation and Management

In Section 6.2 a field length of 60000 octal or 120000 octal was suggested for the two versions of BALM, respectively. Actually BALM uses as much core as it can and is limited only by the amount specified on the job card. If you have written a fairly long BALM program you may need to increase the field length.

BALM has a garbage collector which is invoked each time the system runs out of space. Execution continues as long as the garbage collector is able to recover 1/20 of the total amount of space allotted for data. This limit was put in to prevent the program from calling the garbage again and again without receiving enough space to continue execution. At the end of BALM execution some statistics are printed including the number of garbage collections. The user may assume that each garbage collection takes approximately 1 second on the CDC 6600. If the amount of time spent garbage collecting is more than half of the total execution time, the field length should be increased.

The garbage collector recovers space which was used by BALM items. As soon as a program is finished with a string, list or vector the variable could be set to NIL so that space can be recovered.

Garbage collection takes place automatically but the user may force a garbage collection if he wishes.

GARBCULL() returns NIL, forces a garbage collection.

CHAPTER 7. PROGRAM CONTROL, TRACING AND DEBUGGING

7.1 Controls

BALM execution stops when the compiler encounters an end of file on its input. The user may also cause execution to terminate by using

STOP()

For example

```
IF IND GT LIMIT THEN DO
  PRINT(*NO SOLUTION FOUND*),
  STOP()
END,
```

</

The user may redefine error to suit his own needs. The current procedure is

```
ERROR=PROC(TYPE),
  IF TYPE EQ 3 THEN DO EXECUTE(INPUT,OUTPUT), STOP() END
  ELSE STOP()
END;
```

Execution terminates except when the program attempts to call an undefined procedure. In that case the compiler is called recursively. This has the effect of skipping ahead to read the next card on the input file. Compilation continues from there.

7.2 Debugging Aids

There is a debugging facility in BALM which compiles all procedures with an entry message, a print of arguments, and a message upon return giving the value of the procedure. It also compiles all GOTO's with a print of the label. The user signals that he wishes debugging aids by executing

```
DEBUG();
```

This will affect all procedures compiled from then until an end of file or

```
NODEBUG();
```

is encountered. For example

```
FACT1=PROC(X), IF ZR X THEN 1 ELSE X*FACT1(X-1) END;
```

```
DEBUG();
```

```
FACT2=PROC(X), IF ZR X THEN 1 ELSE X*FACT2(X-1) END;
```

```
PRINT(FACT1(5));
```

```
120
```

```
FACT2(4);
```

```
FACT2 ENTERED
```

```
ARG 1 IS 4
```

```
FACT2 ENTERED
```

```
ARG 1 IS 3
```

```
FACT2 ENTERED
```

```
ARG 1 IS 2
```

```
FACT2 ENTERED
```

```
ARG 1 IS 1
```

```
FACT2 ENTERED
```

```
ARG 1 IS 0
```

```
FACT2 RETURNED 1
```

```
FACT2 RETURNED 1
```

```
FACT2 RETURNED 2
```

```
FACT2 RETURNED 6
```

```
FACT2 RETURNED 24
```

An example of goto tracing is as follows.

```
DEBUG()

BEGIN(FIRST),
FIRST=1,
L, IF FIRST EQ 1 THEN FIRST=FIRST+1 ELSE RETURN TRUE,
GOTO L
END;
GOTO L
```

There are two switches to allow the user to control printouts after the procedures have been compiled with debugging prints:

PRCTRACE
and

GOTRACE
For example

```
DEBUG()

FACT=PROC(X), IF ZR X THEN 1 ELSE X*FACT(X-1) END;
PRCTRACE=NIL
PRINT(FACT(5));
120

PRCTRACE=TRUE;

FACT(2);
FACT ENTERED
ARG 1 IS 2
:
:
:
```

To assist in debugging on the 6600 a user may use the BALM identifier TRACE. The user is cautioned to use this facility only when for some reason he does not wish to recompile. He must be careful to turn TRACE on in the same block as the programs he wishes to trace are executed.

```
DO TRACE=2, ...., TRACE=0 END;
```

This avoids tracing the compiler procedures

TRACE - Default value is 0

1 - messages areprinted from the garbage collector
indicating how many words of heap are used for lists,

vectors, etc. Also a message is printed at each request for more stack or symbol table space.

If a SAVEALL is executed the actual core used and an estimated minimal field length for RESUMEALL are printed.

- 2 - The names of the calling and called procedures are printed each time a call is executed. The names of the returning procedure and the procedure it is returning to and the value returned are printed when a return is executed.
- 3 - Both 1 and 2
- 4 - At end of run a core dump of the MBALM machine is printed.
- 5 - Both 1 and 4.
- 6 - Both 2 and 4.
- 7 - Combination of 1,2, and 4.

There exists a further tracing capability.

<u>Expression</u>	<u>Value</u>
STKTRACE(I)	returns a list of procedures and their arguments as they occur on the stack, i.e. in reverse calling sequence. I defines the depth of the trace. Each member of the list is itself a pair whose head is code and whose tail is a vector containing the arguments.

This is particularly useful when a procedure wishes to know who called it. Suppose you have a generalized message printer

```
MESS=PROC(ARG), BEGIN(N),
      N=STKTRACE(2),
      N=TL N,
      PRINT(HD N, =CALLS,=MESS),
      .
      .
      END END;
```

The arguments in the tree will not generally be meaningful to the user. They come from the stack and are only useful when the system capability of stack variables is used. See Chapter 11 for an explanation.

7.3 Talkative

It is possible to run the BALM compiler in talkative mode. This is useful when studying the compiler. The variable TALKATIV is the switch with which to trigger the printouts.

TALKATIVE - default value is 0

- 1 - the compiler prints a list of global variables used following each compilation
- 2 - the same as the above plus a print of the syntax tree
- 3 - the same as both 1 and 2 plus a print of the syntax tree following macro expansion
- 4 - the same as 1, 2 and 3 plus a print of the MBALM code generated for each statement.

CHAPTER 8. SYNTAX

8.1 Parsing

The compiler consists of three phases, which are called the parser, the macro-expander, and the code generator. The parser transforms an expression into a form called the syntax tree which shows the syntactic structure of the expression explicitly.

To illustrate the form of the syntax tree, consider the following expression.

X * X

The syntax tree of this expression can be represented as

(* X X)

Here we have used the symbols (and) as a form of brackets to group together the components of the expression, with the operator being given first. Any part of a syntax tree between corresponding (and) is called a subtree, and that part of the expression which corresponds to a subtree is called a subexpression. The syntax tree of the expression

X*X+Y*Y

can be represented as

(+ (* X X) (* Y Y))

This shows that the expression is the sum of two subexpressions whose syntax trees are (* X X) and (* Y Y). The expression

has the syntax tree
PRINT(*RESULT*, A*(B+C))

(PRINT (, *RESULT* (* A (+ B C))))

Syntax trees may be printed by setting the switch

TALKATIV=2;

In this example each line input by the user is prefaced by =>.

For example

```
=> TALKATIV=2;
=> A = B + C;
SYNTAX TREE
(= A (+ B C))
```

8.2 Precedence and Associativity

The BALM language is what is sometimes called an operator precedence language. That is, the syntax of the language is determined primarily by specifying a set of operators, and the precedence relations between them. Thus in the expression

$X * X + Y * Y$

the * and + are operators, with the * having higher precedence than +. This means that in an expression of the form

$(A + B) * C$

the parentheses are necessary to associate C with the expression A+B. In BALM every operator has two numbers associated with it, called its left and right precedence. If the right precedence is higher than or equal to the left, the operator is right associative.

$A = B = C = D$ is equivalent to $A = (B = (C = D))$

However + and - which have the same precedence are left associative.

$A - B + C - D$ is equivalent to $((A - B) + C) - D$

Operators in BALM are classified into three types, referred to as infix, unary, and bracket. Infix operators take two arguments, with the operator being placed between the arguments. Examples of infix operators are +, *, =, THEN, etc. Unary and bracket operators are both forms of prefix operators, that is, they take one argument, and are placed before that argument. The difference between a unary operator and a bracket operator is that after the argument of a bracket operator an infix operator is expected. The function of this infix operator is to terminate the scope of the bracket operator. Examples of unary operators are HD, RETURN, and IF. Examples of bracket operators are PROC, BEGIN, and DO, all of which can be terminated by the infix operator END. The whole of the BALM language is defined in terms of these three types of operators, with the exception of parentheses, square brackets, the quote operator, the NOOP operator, and the COMMENT operator. A list of the predefined operators in BALM, together with their precedences, is given in Section 8.3.

The rules for determining whether a symbol is an operator, and whether it is infix or prefix, are as follows.

- (1) An expression must start with an operand or a prefix operator.
- (2) A prefix operator must be followed by another prefix operator or operand.
- (3) An operand must be followed by an infix operator.
- (4) An infix operator must be followed by an operand or a prefix operator (unless it is used to terminate the scope of a bracket operator, in which case it must be followed by an infix operator).

Note that these rules permit the same symbol to be a prefix and an infix operator simultaneously. The determination of the type of an operator is made in a left-to-right scan, so omitting an operator can propagate errors.

8.3 Built-In Operators

Unary and Bracket Operators

<u>Operator</u>	<u>Definition</u>	<u>Precedence</u>
>	Quotation of constants	9999
=	Quotation of constants	9999

(continued)

<u>Operator</u>	<u>Definition</u>	<u>Associativity</u>	<u>Precedence</u>
ELSEIF		right	300
,	Separator	right	100
MEANS	Macro definition	right	0
END	Bracket terminator	right	0
;	Terminator	right	-1

8.4 Examples

The following is a syntax tree from a complete BALM procedure. Lines input by the user are prefaced by =>.

```

=> SUBST = PROC(A,X,L),
=>   IF A EQ L THEN A
=>   ELSEIF NOT PAIRQ(L) THEN L
=>   ELSE SUBST(A,X,HD L):SUBST(A,X,TL L)
=>   END;
SYNTAX TREE (= SUBST (PROC (, (, A (, X L))
(IF (ELSEIF (THEN (EQ A L) A)
(ELSE (THEN (NILQ (PAIRQ L)) L)
(: (SUBST (, A (, X (HD L)))))
(SUBST (, A (, X (TL L)))))))
END))

```

This syntax is considerably more complex than any seen so far. However, if we consider that its form is the same as

A = B

which parses as

(= A B)

we can select and examine subtrees. The first subtree begins with

(PROC ...)

PROC is a bracket operator and it forms a tree like the following.

(PROC (, ARG EXPR) END)

The second subtree following (PROC .. is thus its list of arguments. The third subtree is its expression. If we examine the expression we can see how a conditional parses.

IF COND THEN X ELSE Y

parses as

(IF (ELSE (THEN COND X) Y))

CHAPTER 9. LANGUAGE EXTENSIONS

The BALM system consists of a number of routines, written in BALM, which read, compile, and execute the user's program. There is essentially no distinction between these routines and those which constitute the user's program. In a similar way, there is no distinction between the data-objects manipulated by the user's program, and the data-objects manipulated by the system. This lack of distinction permits the user to modify parts of the system to meet his own needs if necessary. In particular, the user can design his own language by modifying or extending the syntax of BALM. There are certain safeguards built into the system to prevent this being done unintentionally.

The BALM compiler has been designed so that it can be extended in a number of ways. These range from rewriting the compiler entirely, which requires considerable work and knowledge, to rather simple extensions which can be done without extensive knowledge of the workings of the system. We will concentrate on two simple but powerful extendability mechanisms. First, the user can specify new operators, their precedences and the procedures which they should correspond to. Second, the operator MEANS can be used to define new forms of expression in terms of old forms.

9.1 Defining New Operators

The following expressions, when evaluated, will define new operators.

```
UNARY(=OP,LPR,=PR)
BRACKET(=OP,LPR,=PR)
INFIX(=OP,LPR,RPR,=PR)
```

In each case OP is the operator to be defined, and PR is the identifier to be used to represent it in the syntax tree. LPR and RPR are the left and right precedences of the operator.

For example, suppose the user was writing a program in which pairs of items were associated, and the program used lists to specify these associations. The user would probably write procedures to manipulate these lists, so that, for example,

SEARCH(X,L)

would find the item associated with X on the list L. Rather than write this, he could define an operator OF so that he could write

X OF L

The following expression will define the operator

INFIX(=OF,1451,1450,=SEARCH))

The expression

X OF L

will now parse as

(SEARCH X L)

The precedence selected is between the arithmetic and the logical operators. Thus the user may write

IF X+N OF L1 EQ Y*NN OF L2 THEN

which is equivalent to

IF ((X+N) OF L1) EQ ((Y*NN) OF L2) THEN ...

The operator is left associative because its left precedence is greater than its right precedence. Thus

X OF L1 OF L2

is equivalent to

(X OF L1) OF L2

A user may also redefine existing operators. Thus if the user has written a matrix multiply procedure,

```
MMPY= PROC(X,Y),
BEGIN(),
  IF INTQ(X) AND INTQ(Y) THEN RETURN X*Y
  ELSEIF INTQ(X) AND VECTQ(Y) THEN ...
  ELSEIF INTQ(Y) AND VECTQ(X) THEN ....
  ELSEIF VECTQ(X) AND VECTQ(Y) THEN ....
  ELSE DO PRINT(#MULTIPLY ERROR#), RETURN NIL END
END END;
```

he may now change the meaning of * so that

X*Y

parses as

(MMPY X Y)

by writing

INFIX(=*,1601,1600,=MMPY))

Note that as long as MMPY is compiled before the operator is redefined then * will have its former meaning in MMPY. In fact any procedures compiled before * is redefined are not affected. However, suppose the user subsequently discovered an error in MMPY and wished to recompile. He might make the necessary correction and resubmit his deck. However, if he has created

a saved file with a number of procedures or if he is working under time sharing, he may not wish to start fresh. There are two utility procedures which permit a user to remove the most recent definition of an operator.

```
REMINFIX(=OP);  
REMUNARY(=OP);
```

He may therefore execute

```
REMINFIX(=★);
```

and

```
X * Y
```

will again parse as

```
(★ X Y)
```

Now he is ready to redefine MMPY.

USE OF NOOP

Suppose a user defines a new operator

```
(=IN,1451,1450,=IN);
```

and then wishes to associate a procedure with it.

```
IN=PROC(A,B), ..., END;
```

He will receive the following diagnostic from the parser.

```
*** (IMPROPER USE OF IN) ***
```

He could reverse the order and define the procedure before declaring it to be an operator or he could use NOOP.

```
NOOP IN = PROC(A,B), ..., END;
```

NOOP tells the parser to treat the identifier following it as a variable not an operator.

9.2 Macros and Use of MEANS

In an earlier example we defined an operator of so that

```
X OF Y
```

would parse as

```
(SEARCH X Y)
```

Suppose the user writes a procedure which can be used to construct these lists, so

```
L=DEF(X,Y,L)
```

will associate X with Y on list L. However, the user would like to be able to write

```
X OF L = Y
```

to accomplish this. He may make use of macro expansion. The MEANS operator permits the user to specify how an expression in his extended language is to translate into BALM. It takes the form

expr1 MEANS expr2

Macro expansion in BALM takes place after parsing. Thus all operators used in expr1 and expr2 must be defined and both expressions must be acceptable to the parser.

The expression

`X1 OF X2 = X3 MEANS X2 = DEF(X1,X3,X2);`

defines the transformation and the user may now write

`A+10 OF LIST1 =>ALPHA#;`

and it will be transformed to

`(= LIST1 (DEF(,(+A 10) (,LIST1 #ALPHA#)))`

The variables X1,X2, ...X10 play a special part in MEANS. Occurrences of these variables in expr1 match any subexpression in a parsed tree. These subexpressions are then substituted in expr2 of the MEANS. All other variables must appear in a subsequent expression or no transformation takes place.

For example if the user writes

`X OF Y = X1 MEANS Y = DEF(X,Y,X1);`

only expressions containing those variables, such as

`X OF Y = 10;
X OF Y = A+B+C;`

will be transformed. Expression with other variables

`A OF L = 10;
C + D OF LST = X+Y;`

will not be transformed.

Note that if an XI occurs twice or more in expr1, the corresponding subexpressions must be the same. Occurrences of an XI in expr2 which did not occur in expr1 will not be substituted.

As another example of the use of MEANS, suppose the programmer was dealing with two-dimensional arrays implemented as vectors of vectors, and wanted to refer to the (I,J)th element of an array M as M(I,J). Instead of M[I][J], he would do this by first specifying

`X1[X2,X3] MEANS X1[X2][X3];`

In subsequent code expressions matching X1[X2,X3] would be changed to the form X1[X2][X3], so that, for example, ABC[2*K,L+1] would be changed to ABC[2*K][L+1].

The transformations specified by MEANS definitions can be considered to take place during a left-to-right scan over the syntax tree. The actual algorithm used is the following.

- (1) Search the syntax tree from the left until a subtree is found which is matched by the left-hand side of a MEANS definition. If there are two such definitions, choose the most recent.
- (2) Transform the subtree according to the MEANS definition.
- (3) Continue scanning from the start of the subtree just transformed. However, if the first operator in the subtree was not changed by the transformation, only consider MEANS definitions defined before the one just applied for application to this subtree. Subsequent subtrees will be scanned in the regular way.

To illustrate the algorithm let us examine the earlier example

```
SEARCH= PROC(X,Y), ,.... END;
INFIX(=OF,1451,1450,=SEARCH);
DEF=PROC(A,B,C), ,.... END;
X1 OF X2 = X3 MEANS X2 = DEF(X1,X2,X3);
```

If the following statement is encountered

```
A OF LIST3 = A+10;
```

it will parse as

```
(= (SEARCH A LIST3) (+ A 10))
```

The macro expander will check to see if it has patterns starting with =, and will find

```
(= (SEARCH X1 X2) X3)
```

which does match and the syntax tree will be transformed into

```
(=LIST2 (DEF( , A (, (+A 10) LIST3))) )
```

If another MEANS expression is added

```
X1(X2) = X3 MEANS SETLIST(X1,X2,X3);
```

Then when the expression

```
A OF B = C;
```

is encountered, it parses as

```
(= (SEARCH A B ) C)
```

The macro expander first tries to match it against

```
(= (X1 (X2)) X3)
```

and fails. Then it tries to match it against

```
(= (SEARCH X1 X2) X3)
```

finds a match and makes the transformation. Thus the MEANS definitions are applied in the reverse order of definition;

that is, most recent first. The result of this process is a new syntax tree, hopefully in standard form, which is passed to the code generator for compilation.

Note that a MEANS definition in which the left-hand side subtree matches the right-hand side subtree, but not at the top level, will be regarded as inherently recursive and will not be permitted. A diagnostic will be issued. For example

```
X1 = X2 MEANS PRINT(=X1,==,X1=X2);
```

is not allowed for if expanded it would result in

```
(PRINT(, A (, (QUOTE ==) (, PRINT(, A (, (QUOTE ==) (,PRINT ...
```

Both the syntax tree and the expanded tree can be printed by setting

```
TALKATIV=3;
```

There is a predefined procedure which enables a user to remove the most recent macro associated with an operator.

```
REMMACRO(=OP);
```

In order to remove

```
X1(X2) = X3 MEANS SETLIST(X1,X2,X3);
```

the following expression must be executed.

```
REMMACRO(==);
```

At times it is necessary to use a variable in expr2 which does not appear in expr1; for example:

```
INFIX(=T0,1550,1550,=T0))
FOR X1 = X2 TO X3 REPEAT X4 MEANS DO G1=IF X2 LE X3 THEN 1 ELSE -1;
                                         FOR X1=(X2,X3,G1) REPEAT X4
                                         END;
```

For this purpose generated names are provided. Occurrences of G1,...,G9 in expr2 will be replaced by identifiers which are unique for the program in which the expansion occurs.

```
FOR I= 10 TO 1 REPEAT J=J+I;
```

translates into

```
DO **001= IF 10 LE 1 THEN 1 ELSE -1,
                                         FOR I=(10,1,**001) REPEAT J=J+I
                                         END
```

where **001 is the generated name which replaces G1 in the expansion.

Examples

ALTERNATIVE FORMS

The following extensions permit alternative forms for procedure definition and conditionals.

```
X1=PROC(X2),X3,X4 END MEANS X1=PROC(X2),DO X3,X4 END END;
UNARY(=DEFINE,3000,=DEFINE);
DEFINE X1(X2) = X3 MEANS X1=PROC(X2),X3 END;
INFIX(=+,200,200,=+);
X1+X2+X3 MEANS IF X1 THEN X2 ELSE X3;
```

The following extension will permit the use of an arbitrary identifier as an operator of high precedence.

```
INFIX(=,,3000,3000,=,);
X1,X2 MEANS X1(X2);
UNARY(=,,3000,=,);
,X1 MEANS X1;
```

For example, this would permit the programmer to write PRINT.A instead of PRINT(A).

DEBUGGING

The following extensions will print out a trace of assignments and jumps

```
X1=X2 MEANS X1=PRINT(=X1,==,X2);
GO X1 MEANS GO DO PRINT(=GO,=X1), X1 END;
```

If required, these could be made more specific, so that only selected variables or labels were traced. The following extension will permit a selected procedure to be traced by preceding its definition with the operator trace.

```
UNARY(=TRACE,3000,=TRACE);
TRACE X1=PROC(X2),X3 END MEANS
X1=PROC(X2), Dn PRINT(=X1,=ARGS,X2),
PRINT(=X1,=VALUE,X3) END END;
```

The following extension will generate traceable versions of all subsequently defined procedures.

```
TRACE(TRUE) MEANS
X1=PROC(X2),X3 END MEANS
X1=PROC(X2), IF MEMBER(=X1,TRACELIST) THEN
DO PRINT(=X1,=ARGS,X2),PRINT(=X1,=VALUE,X3) END
ELSE X3 END;
```

Those procedures will be traced whose names are on the list TRACELIST.

MORE POWERFUL LOOPS

The following expressions permit more powerful forms of loops, with the loop variable modification not restricted to integer steps.

```
INFIX(=WHILE,500,500,=WHILE)
FOR X1=X2 THEN X3 WHILE X4 REPEAT X5      MEANS
    DO X1=X2, WHILE X4 REPEAT DO X5, X1=X3 END END;
```

This permits expressions such as

```
FOR L=LL THEN TL L WHILE L NE NULL REPEAT PRINT(HD L);
```

which will print the members of list LL.

OPERATORS AS PROCEDURES

The following extensions permit unary and prefix operators to be manipulated as procedures.

```
UNARY(=PRF,3000,=PRF);
PRF=X1      MEANS  PROC(X),X1(X)END;
UNARY(=INF,3000,=INF);
INF=X1      MEANS  PROC(X,Y),X1(X,Y)END;
```

STRUCTURES

The following extensions permit the definition of structures, implemented as vectors with named components.

```
UNARY(=STRUCTURE,3000,=STRUCTURE);
STRUCTURE X1(X2)      MEANS
    DO (X1(X4)) MEANS VECTOR(X4)), COMPONENTS((1,2,3,4,5),X2) END;
COMPONENTS(X1,X2)    MEANS
    DO (X2(X4)) MEANS X4[X1]), (X2(X4)=X3 MEANS X4[X1]=X3) END;
COMPONENTS((X1,X5),X2)  MEANS
    DO (X2(X4)) MEANS X4[X1]), (X2(X4)=X3 MEANS X4[X1]=X3) END;
COMPONENTS((X1,X2),(X3,X4))  MEANS
    DO COMPONENTS(X1,X3), COMPONENTS(X2,X4) END;
```

As defined here this is limited to structures with up to five components. An alternative definition which permits an arbitrary number of components is defined

```
STRUCTURE X1(X2)      MFANS
    DO (X1(X4)) MEANS VECTOR(X4)), COMPS(X2) END;
COMPS(X1)      MEANS  COMPS2(=X1);
COMPS1(X1,X2)  MEANS  COMPS2(=X1,X2);
RECURSIVE(X1)   MEANS  X1;
COMPS1((X1,X2),X3)  MEANS  RECURSIVE(COMPS1(X2,(=X1,X3)));
COMPS(X1,X2)   MEANS  COMPS1(X2,=X1);
COMPS2 = PROC(), BEGIN(I), FOR I=(1,NUMARGS()) REPEAT DO
    TRANSLATE(LIST(ARGUMENT(I),=(X1),=MEANS,=X1,VECTOR(I))), 
    TRANSLATE(LIST(ARGUMENT(I),=(X1),==,=X2,=MEANS,
                    =X1,VECTOR(I),==,=X2))
END END END;
```

CASE EXPRESSIONS

The following extensions permit a form of conditional expression called a CASE expression.

```
BRACKET(=CASE,100,=CASE)
INFIX(=ESAC,99,99,=ESAC)
CASE X1 IN X2 ESAC MEANS VECTOR(PROCS(X2))[X1]()
PROCS(X1) MEANS PROC(),X1 END;
PROCS(X1,X2) MEANS (PROC(),X1 END, PROCS(X2));
```

This will permit expressions such as

```
CASE MONTH IN (31,28,31,30,31,30,31,31,30,31,30,31) ESAC
```

Note that the implementation of the CASE expression as a vector of procedures will not permit the use of jumps in the list of expressions. This requires a more elaborate implementation.

PATTERN MATCHING

The BREAKUP procedure can be made available in a convenient format by the following definition.

```
=X1=X2 MEANS BREAKUP(=X1,X2);
```

This permits expressions such as

```
WHILE =(H,L)=L REPEAT PRINT(H)
```

which will print the elements of the list L.

OPERATOR DEFINITION

A convenient form for defining operators of high precedence can be defined

```
INFIX(=,,3000,3000,=,);
UNARY(=OPERATOR,=100,=OPERATOR);
OPERATOR X1,X2 = X3 MEANS
  DO X1=PROC(X2),X3 END, UNARY(=X1,3000,=X1) END;
OPERATOR X1,X2,X3 = X4 MEANS
  DO X2=PROC(X1,X3),X4 END, INFIX(=X2,3000,3000,=X2) END;
```

This will permit operators to be defined in the following ways.

```
OPERATOR X.SUMSQ,Y = X*X+Y*Y;
OPERATOR SIGN,X = IF X GE 0 THEN 1 ELSE -1;
```

ALGEBRAIC MANIPULATION

The following definitions will permit the user to do algebraic manipulation.

```
UNARY(=LET,3000,=LET);
LET X1=X2 MEANS X1=SYMB(X2);
SYMB(X1) MEANS X1;
UNARY(=$,3000,=$);
SYMB($X1) MEANS CONSTSYMB(=X1);
SYMB(X1+X2) MEANS ADDSYMB(SYMB(X1),SYMB(X2));
SYMB(X1*X2) MEANS MPYSYMB(SYMB(X1),SYMB(X2));
```

This will translate, for example, the expression

```
LET X=2★Y+4★$A;
```

into the same code as

```
X=ADDSYMB(MPYSYMB(2,Y),MPYSYMB(4,CONSTSYMB(=A))));
```

9.3 Lexical Changes

The lexical scanner is that part of the BALM system which determines that

123ABC

is two items, the integer 123 and the name ABC, whereas

ABC123

is one item, a name. The rules for lexical scanning can be varied to a degree by the user if his extended language does not conform to BALM scanning rules.

The BALM system divides the characters into the following classifications.

Letters	A - Z
Numbers	0 - 9
Special	All others

The user may change a character from one class to another. Each class is associated with a number; letters are 10, specials are 11 and numbers have their integer value, 8 is 8, 4 is 4, etc. A procedure has been provided which allows the user to change a character from one class to another.

```
CHGCHAR(=CHAR,CLASSNO);
```

Thus

```
CHGCHAR(=-,10);
```

adds - to the letters and removes it from the special characters.

Names like

```
A-NAME
ITEM=A
```

are now acceptable.

BALM scanning rules are as follows.

- (1) An integer is begun by a digit and terminated by a letter or special (the letter B is considered part of the number and denotes octal)
- (2) A name begins with a letter and is terminated by a special character.
- (3) Special characters combine with nothing and are considered to be one character names, except for space which is ignored.

In addition two other classifications of special characters exist but are not used by the BALM compiler. They are included to give BALM users additional flexibility in extending the language. Characters with a value of 12 act as terminators. That is they can appear as the last character of an identifier. For example, if HD. and TL. are unary operators and . has a value of 12 then a user can write

HD.TL.Y

without spaces and the lexical scanner will return the 3 appropriate items. A value of 13 denotes a combining special character. It will concatenate only with other characters in its class. For example if * is given a value of 13 then the operator ** can be defined

```
CHGCHAR(=*,13);
INFIX(**,1601,1600,=+);
```

permits a user to write

A=A**2

as an alternative way of denoting exponentiation.

9.4 Adding or Modifying Code Generators

Adding a new code generator is more difficult and requires a more thorough knowledge of the BALM system than the extensions described in the previous sections. In the next section we present an outline of the code produced by the generators present in the current system.

In Chapter 10 a description of the MBALM machine is presented. The code produced by the generators is either calls on BALM system procedures or MBALM machine operations. The main code generator procedure is COMP which is called recursively and compiles code for each BALM expression and subexpression in the expanded tree.

The code generator is driven by two lists CODEGENLIST and OPLIST. These lists are created by procedures INITCODG and INITOPL.

Procedure COMP examines each node of the tree to see if the operator appears on the CODEGENLIST. If it does, the procedure associated with that operator is called with the tree as an argument. If the operator on a node is not on the CODEGENLIST, it is assumed to be either an expression whose value is a code block or an MBALM operation. In this case COMP calls procedure CALLS.

Procedure CALLS checks to see if the operator on the code is a member of the OPLIST. If it is, the MBALM operation code associated with it is generated. Otherwise code to evaluate it is generated. The result is assumed to be a code block, and a call to that code block is generated.

Setting switch TALKATIVE=4 produces a listing of the generated MBALM code as well as the parsed and expanded trees.

9.5 Code generated for BALM Expressions

An informal outline of the way the compiler works is given below. This shows the correspondence between a BALM expression and the code compiled for it. In each case the code compiled will stack the value of the expression. The procedure that does this in the compiler is called COMP. In some cases COMP invokes other procedures to process particular expressions. The names of these procedures are given below also.

CHAPTER 10. THE MBALM MACHINE

The BALM system is designed around a virtual machine called the MBALM. Both the system routines and the user's routines are translated into machine code for this machine prior to execution. The code for the MBALM machine is executed by simulation on the target machine, or by translation into the machine code of the target machine. The BALM system is designed so that the expert user can make use of a knowledge of the MBALM machine code, but need not know how the MBALM machine is implemented.

The memory of the MBALM contains three components, called the stack, the heap and the symbol table. The basic data-object of the MBALM is called an item, and is an ordered pair whose components are called TYPE and INF. The HEAP and the STACK are ordered sets whose members are integers or items. The type of an item is either INT, LOG, ID, STR, PAIR, VECT, CODE, or LBL. The INF component of an item of TYPE INT, LOG, or LBL is an integer. The INF component of an item of TYPE STR, PAIR, VECT, or CODE is an index into the HEAP. The INF component of an item of TYPE ID is an index into the symbol-table. The symbol-table is a set of ordered triples, the components of the triples being called the name, the value, and the property-list. The NAME component is an item of TYPE STR, while the VALUE and property-list components are items.

For convenient we will use the following notation to refer to the components of items and symbol-table elements. If ITM is an ITEM, its components are referred to as ITM.TYPE and ITM.INF. If SYMB is an element of SYMTAB, its components are referred to as SYMB.NAME, SYMB.VALUE, and SYMB.PROPL. Assignment to these components is assumed to change no other elements of the stack, symbol-table or heap. An item whose TYPE and INF components are T and I is written ITEM(T,I).

10.1 Definition of Operations

In the definition of MBALM instructions given below, the following representations are used.

S	a vector representing the stack
HEAP	a vector representing the heap
SYMTAB	a vector representing the symbol-table

The MBALM is conveniently defined using a number of variables whose values are integers, and which might be considered to be registers.

P0	the index in the heap of the current procedure
PA	the relative address of the current instruction
ST	the index of the top element of the stack
AB	the index in the stack of the zeroth argument
NA	the number of arguments
VB	the index in the stack of the zeroth variable
NV	the number of variables
NS	the number of symbol-table entries.

The following expressions are used in defining the instructions.

PUSH(X)	add X to the top of the stack
POP(X)	remove the top of the stack and assign it to X
POP()	removes the top of the stack and returns its value
CHECK(T1, ..., TN)	check that the items at the top of the stack are of types T1, ..., TN with TN being the top
CHECKEITHER(T1, ..., TN)	check that the item on the top of the stack has one of types T1, ..., TN
INT, LOG, ID, STR, PAIR, VECT, CODE, LBL	mutually distinct integers used to distinguish types
ANY	value assumed to specify arbitrary type
LSBYTE(N)	returns I modulo 128
PARAM(I)	the integer value of the I bytes following the current instruction
GETHEAP(N)	returns the index in HEAP of a block of N consecutive unused locations
GETID(STRING)	returns the index in SYMTAB of the entry whose name component contains the same characters as STRING. If there is no such entry, creates one and returns its index.

The format used for defining the various operations of the MBALM is the following

OP(I), ... , ... ;

This represents the sequence of operations which must be executed for the instruction whose opcode is I.

The BALM code below represents an actual model of the MBALM machine. If this code is compiled the user can execute a file of MBALM instructions. Assume FORTRAN file 9 contains MBALM code. Then the following BALM instructions will load and execute it.

```
BINF=MAKFILE(9,72);
SETUP(10000,1000,500);
LOADER();
MBALMSIM();

```

To illustrate the sort of code used in the MBALM,
consider the following BALM procedure.

```
SUMV=PROC(V), BEGIN(S,I,N),
  N=SIZE(V), S=0, I=1,
  NXT, IF I GT N THEN RETURN S,
  S=S+V[I], I=I+1, GOTO NXT,
END END;
```

This procedure computes the sum of the elements of a vector V,
assumed to be integers. The MBALM code produced for this
procedure is as follows.

#	BYTE	OP,	INST,	OPERAND	#
#	38	33R	* ARG I1	* 1B

HEAP(IP)=LEN, SYMTAB[ISAV].VALUE=ITEM(CODE,IP),
GOTO STRT
END END;

```

Input to the loader is a series of lists of MBALM instructions representing procedures. The loader locates each name in the symbol table and if not there makes an entry. It generates code blocks with each occurrence of a name replaced by its symbol table entry number. MBALM instructions are assumed to be in seven bit bytes. Thus the number 256 is represented by two bytes

0000010 0000000

or in octal

28 08

For example, loading a constant 256 requires the following 3 byte MBALM instruction

48 28 08

The input to the loader for the example from the end of the previous section is as follows.

```
( 08 SUMV 33B 18 5B 0B V 34B 18 6B 0B V 35B 18 36B 3B  
5B 0B S 32B 18 5B 0B I 32B 2B 5B 0B N 32B 33B 137B

35B 1B 31B 3B 6B 0B N 35B 1B 131B 33B 1B 5B 0B V  
34B 1B 35B 1B 6B 0B V 35B 1B 115B )
```

GARBAGE COLLECTOR

The garbage collector is not illustrated here as there are sufficient discussions of garbage collectors elsewhere. Whenever GETHEAP is unable to fulfill a request the garbage collector is invoked. The garbage collector scans the value and type entries of the symbol table and the stack. It flags each heap entry pointed to from the stack and symbol table. Unused heap entries are recovered and reused.

10.3 Bootstrapping

The BALM system consists of two separate modules. The first module is the system itself written in BALM, and containing I/O routines, lexical scanner, a parser, a code generator and various utility routines. This module is machine independent

in that the code generator produces code for a virtual machine called the MBALM. The second module is a mechanism for executing the MBALM machine code. This module is different for each target machine. There are MBALM simulators available for the CDC 6600, the IBM 360, the UNIVAC 1108, XDS SIGMA 5, and the DEC PDP10. An execution module which translates the MBALM code into machine code is also available for the CDC 6600.

Bootstrapping is the process by which a compiler moves itself from one machine or system to another. Since the BALM compiler is written in BALM, the compiler is capable of compiling itself. To implement BALM on a new computer requires

- (1) writing a program to execute MBALM instructions, i.e.
an MBALM simulator
- (2) writing a loader program to read MBALM instructions
and create code blocks and symbol table entries.
- (3) writing a garbage collector
- (4) a file of MBALM code produced by compiling the BALM
compiler. The listing of the BALM system in Appendix F
is preceded by a procedure called bootstrap which
generates such a file.

Once the loader has read the MBALM instructions, execution begins with the first procedure loaded. This is procedure BALM. It calls INITIATE which in turn calls various procedures necessary to initialize the system: see the flow diagram in Chapter 11. One of these, INITIO, defines the BALM character set for the new machine by reading 3 cards. These cards are the first cards in the BALM supplement. The characters start in column 2 and the first character on the first card is a space.

```
.+-#{}[]-$,:+£/≥!  
0123456789  
ABCDEFGHIJKLMNPQRSTUVWXYZ
```

The special characters appear on the first card. They are in a predefined order so that if one wishes to use a character other than ; for a terminator it should appear in column 21. The second card contains the numbers 0-9 in ascending order. The third card contains the alphabet in alphabetical order but may include special characters at the end. These characters will then be considered as part of the alphabet in forming names.

This section is intended to be a guide to the source listing which is included in Appendix F. It is directed to the user who wishes a more detailed knowledge of the system in order to extend the compiler. Several features about the compiler require some explanation. Originally all compiler procedures and variables were accessible to the user. This turned out to be quite unsatisfactory because it led to inadvertent modification of the compiler. If a user selected the name BLANK and used it as a variable he would begin getting strange diagnostics because the lexical scanner uses the predefined variable BLANK. To protect a BALM user from these types of problems all critical variables and procedures have a name which includes a special character. In order to compile the BALM compiler . must be treated as a letter, as described in Section 9.3. The way to do this is

`CHGCHAR(=,,10);`

Thus a user is protected from inadvertent modification of the compiler since before he can form names with . he must change . to a letter.

11.1 Very Local Variables

Name scoping is described in Chapter 3. Let us review for a moment what happens when a procedure

`SUMSQ=PROC(X,Y), X*X+Y*Y END;`

is called, as follows:

`A=SUMSQ(3,4);`

The following steps are involved:

- (1) save the current values of X and Y
- (2) assign 3 to X and 4 to Y
- (3) evaluate the expression
- (4) restore the original values of X and Y
- (5) return the value of the procedure -- given in step 3.

Entering a block of code with local variables is quite similar.
Execution of

```
BEGIN(A,B),  
      ;  
      ;  
END;
```

involves the following steps.

- (1) save the current values of A and B
- (2) evaluate the expressions in the block
- (3) restore the original values of A and B
- (4) value of the block is either the value of the last expression or the argument of a return.

Note that in the case of a procedure steps 1, 2 and 4 involve saving and restoring of values; in the case of a block steps 1 and 3. The values are saved in the stack. Each time a procedure or block is entered the stack is used to save these values. Upon exit the stack is popped after values are restored. The code generated to perform the saves and restores takes up both extra time and space. It can be eliminated when blocks and procedures access the stack directly for their local variables and arguments respectively. The compiler procedures and blocks do, in fact, access the stack directly. We shall refer to arguments and variables which exist in the stack as very local. The user may request very local as an option by executing

```
MAKALOCAL(TRUE);
```

for very local arguments and

```
MAKVLOCAL(TRUE);
```

for very local variables.

```
MAKALOCAL(NIL); and MAKVLOCAL(NIL);
```

return the system to its normal state.

A very local variable or argument is known only within its own block or procedure. This means that blocks defined within other blocks do not have access to each other's very local variables, after executing MAKVLOCAL(TRUE); and MAKALOCAL(TRUE); arguments and variables prefaced by \$ when defined are treated in the normal way. If they appear without a \$ they are considered to be very local. For example:

```
BEGIN ($A,B,$C,D)
```

A and C will be treated as local and B and D are very local.

```
TEST=PROC($A,B,C)
```

A will be treated normally, B and C are very local -- i.e. known only within procedure TEST.

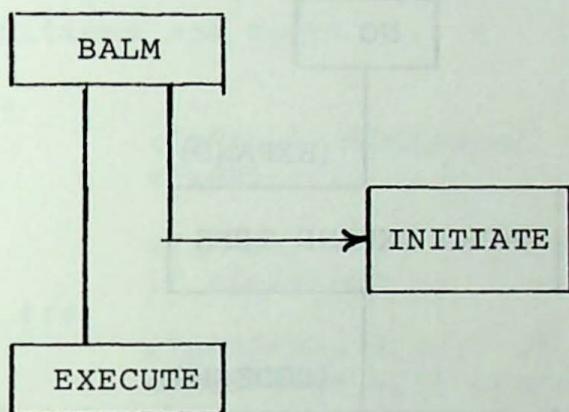

```
MAKVLOCAL(TRUE);  
A=10;  
BEGIN(A), A=1,  
BEGIN(), PRINT(A) END,  
PRINT(A)  
END;
```

will result in the following prints

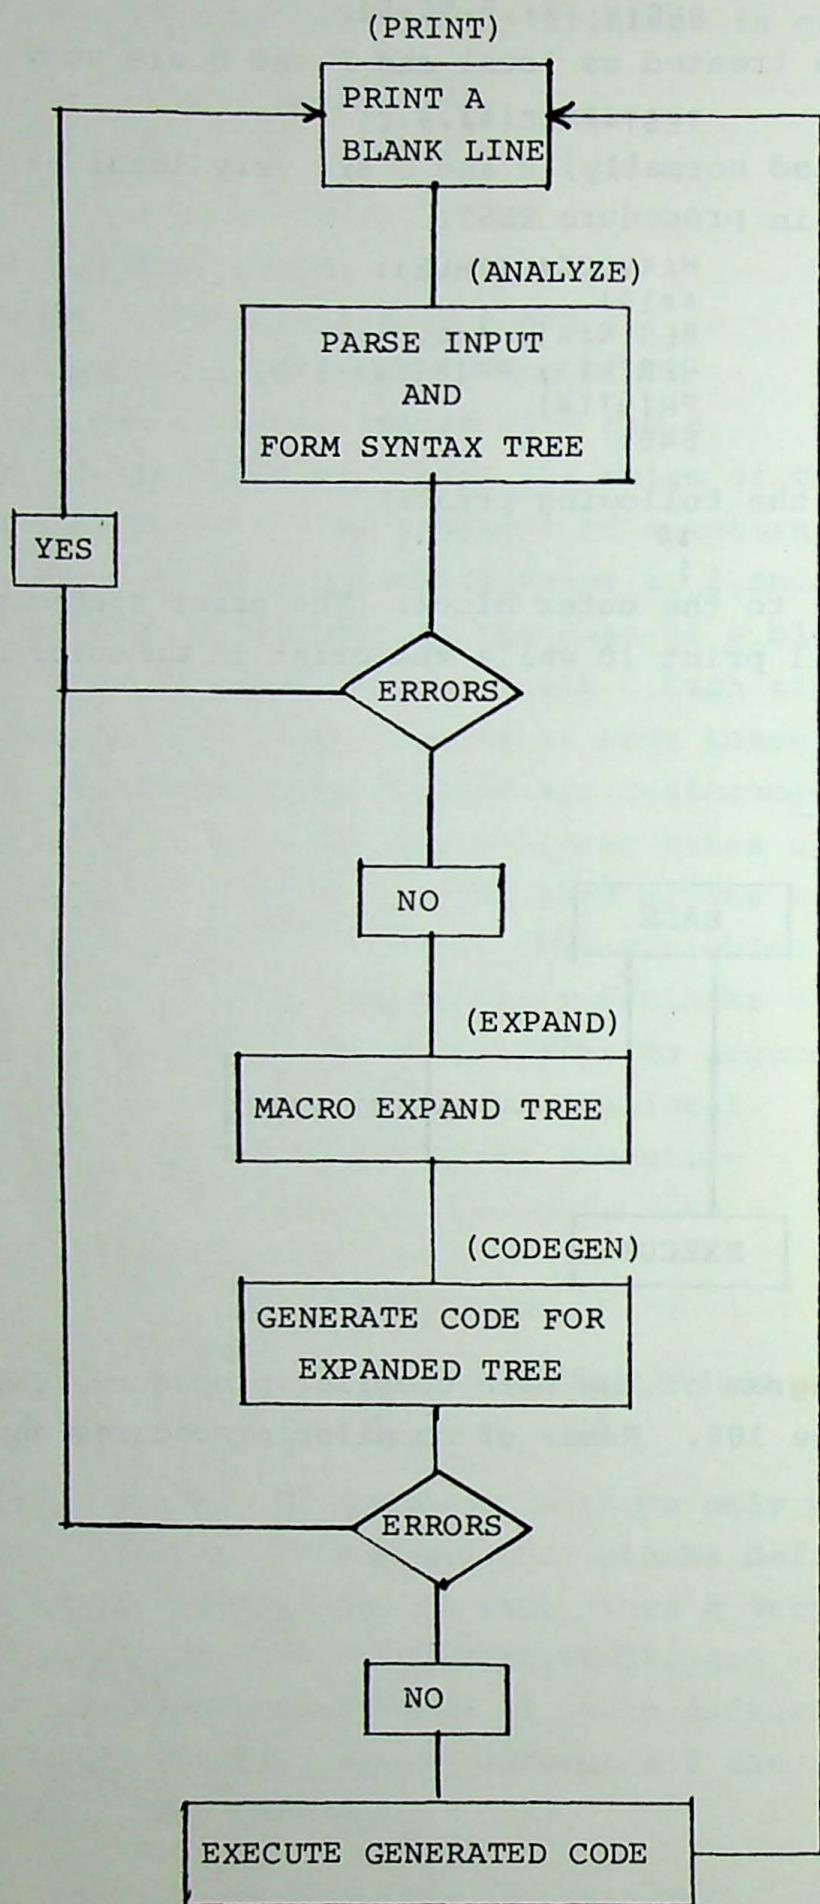

```
10  
1
```

A is very local to the outer block. The print statement in the inner block will print 10 while the print in the outer block will result in 1.

11.2 Flow Chart

The flow diagram of the main compiler procedure, EXECUTE, is given on page 106. Names of compiler procedures appear in parentheses.

APPENDIX A. PARTIAL SYNTAX

We give below a partial definition of the syntax of BALM programs. This is incomplete in the following senses. First, this definition includes programs which are syntactically incorrect. For example, the definition does not prevent the use of expressions which have values of the wrong type, such as as HD 123. This cannot be done in general by syntactic definition, so we have not attempted it at all. Second, there are valid programs which do not conform to the definition. This does not reduce the power of the language very much, and those who wish a more exact definition can consult the more precise definition given elsewhere. Third, the use of blanks in the language is given informally below.

The alternative definitions are given on separate lines, rather than being separated by an alternation mark as is usual. Main definitions are given starting in column 1, while subsidiary definitions are inset.

```
<PROGRAM> ::=  
    <EXPR> ; <PROGRAM>  
    <EXPR>  
<EXPR> ::=  
    <EXPR2>  
    IF <ELSEXPR>  
<ELSEXPR> ::=  
    <THENEXPR> ELSEIF <ELSEXPR>  
    <THENEXPR> ELSE <EXPR>  
<THENEXPR> ::=  
    <EXPR2> THEN <EXPR2>  
<EXPR2> ::=  
    <EXPR3>  
    WHILE <WHILEXPR>  
    FOR <FOREXPR>  
    GO <EXPR3>  
    GOTO <EXPR3>  
    RETURN <EXPR3>  
<WHILEXPR> ::=  
    <EXPR3> REPEAT <EXPR2>  
<FOREXPR> ::=  
    <FORASS> REPEAT <EXPR2>  
<FORASS> ::=  
    <NAME> = <FORLIST>  
<FORLIST> ::=  
    ( <FORPARAMS> )  
<FORPARAMS> ::=  
    <EXPR> , <EXPR>
```

```

<EXPRS> ::= <EXPR> , <EXPRS>
<EXPR3> ::= <EXPR> , <EXPR>
<EXPR4>
<LHS> = <EXPR4>
<LHS> ::= <NAME>
          HD <EXPR13>
          TL <EXPR13>
          VALUE <EXPR13>
          <EXPR14> ( <EXPR> )

<EXPR4> ::= <EXPR5>
<EXPR5> ::= <EXPR4>
<EXPR6>
<EXPR6> OR <EXPR5>
<EXPR7>
<EXPR7> AND <EXPR6>

<EXPR8>
<EXPR8> ≡ <EXPR8>
<EXPR8> EQ <EXPR8>
<EXPR8> NE <EXPR8>
<EXPR8> GT <EXPR8>
<EXPR8> GE <EXPR8>
<EXPR8> LT <EXPR8>
<EXPR8> LE <EXPR8>
<EXPR8> SIM <EXPR8>

<EXPR8>
<EXPR9> + <EXPR9>
<EXPR9> - <EXPR9>

<EXPR10>
<EXPR9> * <EXPR10>
<EXPR9> / <EXPR10>

<EXPR11>
- <EXPR11>

<EXPR12>
<EXPR12> + <EXPR11>

<EXPR13>
SIZE <EXPR13>

<EXPR14>
HD <EXPR13>

```

```

TL <EXPR13>
VALUE <EXPR13>

<EXPR14> ::=

<CONST>
<NAME>
<NOOP> <OP>
( <EXPR> )
<EXPR14> ( <EXPRLIST> )
<EXPR14> [ <EXPR> ]
DO <EXPRLIST> END
BEGIN <BLOCKBODY> END
PROC <PROCBODY> END

<EXPRLIST> ::=

<EXPR>
<EXPR> , <EXPRLIST>

<BLOCKBODY> ::=

<LOCALVARS> , <EXPRLIST>

<LOCALVARS> ::=

( )
( <VARLIST> )

<VARLIST> ::=

<NAME>
<NAME> , <VARLIST>

<PROCBODY> ::=

<ARGLIST> , <EXPR>

<ARGLIST> ::=

( )
( <VARLIST> )

<NAME> ::=

<LETTER> <LETTERORDIGIT>

<LETTERORDIGIT> ::=

<EMPTY>
<LETTER> <LETTERORDIGIT>
<DIGIT> <LETTERORDIGIT>

<CONST> ::=

<INTEGER>
<LOGICAL>
<STRING>
= <ITEM>

<INTEGER> ::=

<DIGITS> <DIGITS>

<DIGITS> ::=

<EMPTY>
<DIGIT> <DIGITS>

<LOGICAL> ::=

TRUE
NIL

<STRING> ::=

* <CHARACTERS> *

```

```
<CHARACTERS> ::=  
    <EMPTY>  
    <CHARACTER> <CHARACTERS>  
  
<ITEM> ::=  
    <INTEGER>  
    <LOGICAL>  
    <STRING>  
    <NAME>  
    <SPECIAL CHARACTER>  
    <VECTOR>  
    <LIST>  
  
<VECTOR> ::=  
    [ <ITEMS> ]  
  
<LIST> ::=  
    ( <ITEMS> )  
  
<ITEMS> ::=  
    <EMPTY>  
    <ITEM> <ITEMS>
```

The above definition makes no reference to blanks. A blank terminates a <NAME>, an <INTEGER>, a <LOGICAL>, or a <NAME> used as an operator (such as GT). Otherwise, blanks are ignored except in <STRING>s. Note that <OP> is not defined above, but is intended to refer to any operator. Thus the NOOP operator permits operators to be used also as <NAME>s if necessary. <NAME>s and <SPECIAL CHARACTER>s occurring in <CONST>s are used to represent identifiers of the same name.

APPENDIX B. OTHER VERSIONS

360 Operation

The following control cards are necessary to run BALM programs on the 360 at the School of Commerce (NYU).

```
//NAME      JOB
//          EXEC  BALM4
//BALM4,SYSIN DD  *
               BALM PROGRAM
/*
```

If a user wishes to create a saved file he needs to include a DD card for that file. If his BALM program has a SAVEALL(N) then

```
//BALM4,FTONF001 DD ETC.
```

must be included. A SAVEALL file requires about 20 tracks and RECFM=VS.

APPENDIX C. EXAMPLES

Example 1

When a function is used frequently with a small number of arguments, it can be more efficient to save previous results in a list and look in this list to see if the result has been calculated for this argument already. If the function is FN, instead of FN(X) we can write MEMO(FN,FNL,X), where FNL is the list used to keep the values calculated for FN.

MEMO can be written:

```
MEMO = PROC(FN,FNL,X),
      BEGIN(FNLPR,SAVE,FNLB,FNLPR2),
      FNLB=FNL, FNL = TL FNL, FNLPR=FNL,
      NEXT, IF HD HD FNL EQ X THEN GOTO FOUND,
      FNLPR2=FNLPR,
      FNLPR = FNL, FNL= TL FNL,
      IF NULL(FNL) THEN GOTO NOTF ELSE GOTO NEXT,
      FOUND, IF FNLPR EQ FNL THEN RETURN TL HD FNL,
      SAVE = HD FNL, HD FNL = HD FNLPR,
      HD FNLPR = SAVE, RETURN TL SAVE,
      NOTF, TL FNLPR2 = NIL, SAVE = FN(X),
      TL FNLB = (X;SAVE);TL FNLB, RETURN SAVE
      END END;
```

It is assumed that FNL has been initialized to a list of the form:

(Z (X₁,Y₁)(X₂,Y₂) ... , (X_N,Y_N))

where Y₁=FN(X₁), and N is the number of arguments that it has been decided to save. The HD of the list, Z, is not used by this routine, but may be useful for other purposes. Each argument, written as X above, is first looked up in this list. If it is found, the corresponding pair is moved one place nearer the beginning of the list and the stored value is returned. If it is not found the last pair in thelist is deleted and a new pair corresponding to the new argument is added to the beginning.

An alternative way of writing this function uses a vector to store the argument-value pairs. We will assume that this is of the form:

((X₁,Y₁) (X₂,Y₂) ... , (X_N,Y_N))

The function can then be written as follows.

```

MEMO = PROC(FN,FNL,X),
BEGIN(L,I),
    L=LENGTH(FNL), I=1,
NEXT, IF I GT L THEN GOTO NOTF
      ELSEIF X EQ HD FNL[I] THEN GOTO FOUND,
      I=I+1, GOTO NEXT,
FOUND, IF I EQ 1 THEN RETURN TL FNL[I],
      L=FNL[I], FNL[I] = FNL[I-1],
      FNL[I-1] = L, RETURN TL L,
NOTF, FOR I=(L-1,1,-1) REPEAT FNL[I+1] = FNL[I],
      L = FN(X), FNL[1] = X:L, RETURN L
END END;

```

Note that this probably executes a little more slowly than the other version particularly when the argument is usually not found, because the operation of moving down all the elements of FNL is much slower. However, by a slight modification to this version, an extra entry in the vector, say the first, could be used to keep the index of the top element, and the vector could be treated as circular, with the Lth element being followed logically by the second. This would eliminate the time-consuming move operation.

There are of course several alternative algorithms which may be equally effective. For example, it may be more appropriate to store any new value at the end of the list rather than the beginning, or possibly in the middle. This will be preferable when the arguments fall into two types, a few of which occur frequently, and many of which are rarely repeated.

Example 2

We give below a generalized game-playing routine BEST, using an alpha-beta minimax search, with the appropriate routines POSSMOVES, NEWPOSN, and SCORE added. It will play tic-tac-toe, checkers, chess, or Go with varying degrees of success.

Arguments to BEST are: POSN, the position from which the name must be made; DEPTH, the number of moves the routine should look ahead; WISB and HYB, the range between which scores are acceptable, with HISB being the minimum and HYB the maximum, large scores being good. For tic-tac-toe, for instance, POSN is of the form:

[[X--][-0-]---]X

the extra X indicating it is X to move.

The full deck to play a complete game of tic-tac-toe against itself is constructed as follows:

A123456,CM60000, HARRISON
CIMGET(BALM4,BLM4SVD)
BALM4.

-- GREEN END OF RECORD CARD --
COMMENT (TEST PROGRAM - TIC-TAC-TOE PLAYER)

```
BEST=PROC(POSN,DEPTH,HISB,MYB),  
    BEGIN(ML,DM1,BESTSC,BESTM,TRY),  
    IF DEPTH=0 THEN RETURN(-SCORE(POSN):NIL:NIL),  
    ML=POSSMOVES(POSN),  
    DM1=DEPTH-1,BESTSC=MYB,BESTM=NIL,  
    NXT, IF ~ML THEN RETURN(-BESTSC:BESTM:NIL),  
    TRY=BEST(NEWPOSN(POSN,HD ML),DM1,-BESTSC,-HISB),  
    IF HD TRY GT BESTSC THEN  
        DO BESTSC=HD TRY,BESTM=HD ML END,  
    IF ~ BESTSC LT HISB THEN RETURN(-BESTSC:BESTM:NIL),  
    ML=TL ML, GO NXT  
    END END;
```

```
SCORE=PROC(P),  
    BEGIN(ROWSC,M,H,I,J),  
    ROWSC=PROC(INIT,STEP),

            ELSE L=TL L,
        RETURN NIL
    END END;

```

APPENDIX E. UTILITY PROCEDURES

The predefined procedures in the current system, in alphabetical order, are as follows.

ADDON(LST,X)

S is an arbitrary item and LST points to the last element in a list. The last element is replaced by X:NIL, which is returned as the value of ADDON.

Example: L=LAST= =A:NIL, LAST=ADDON(LAST,=B)

L contains (A B) and LAST is =B:NIL

BRACKET(OP,PREC,PROCNAM)

defines OP as a bracket operator with precedence PREC and associated procedure name PROCNAM.

BREAKUP(PATRN,ARG)

BREAKUP performs a multiple assignment of the names in PATRN to structures in ARG. For example

BREAKUP($\geq(A [B C (D)])$, $\geq(<STR> [57 (X) (Y)])$)

will cause the same assignments as A=<STR>;B=57;C= $\geq(X)$;D= $\geq Y$;

In general, the names in PATRN are assigned values which are the elements appearing in corresponding positions in ARG. If such an assignment cannot be performed due to a difference in structure between PATRN and ARG then NIL is returned, otherwise TRUE. In the case of an assignment failure, only those names encountered before the structural discrepancy will be assigned values. For example,

BREAKUP($\geq(A (B C))$, $\geq(X (3 4))$)

will return TRUE and result in the following assignments.

A= $\geq X$;B=3;C=4;

BREAKUP($\geq(A(B C) D)$, $\geq(X (3 4 5))$) will return NIL and cause the same assignments as the previous example. D will remain unchanged. Constants appearing in PATRN must exactly match their corresponding elements in ARG for a successful match.

BREAKUP($\geq(A B C <STR> 7)$, $\geq(1 2 3 <STR> 7)$) will return TRUE while

BREAKUP($\geq(A B C <STR> 7)$, $\geq(4 5 6 <STR> 8)$) will return NIL.

A constant name or structure can be represented by PATRN by preceding it with a g.

Example:

BREAKUP($\geq(A \geq B B \geq(C D)), \geq(1 B 5 [C D]))$

will return TRUE and will perform the assignments $A=1; B=5;$

BREAKUP($\geq(A \geq B C), \geq(1 (B) <XYZ>))$

will return NIL and will perform the assignment $A=1;$

CHGCHAR(CHAR,N)

CHAR is a vector each item of which represents a character. It is used by procedure LXSCAN to determine BALM items. If the value of an item of CHAR is 0 to 9 the character is than number; 10 the character is a letter; 11 a special character. CHGCHAR changes the value of the CHAR item representing CHR to N. For example,

CHGCHAR(=,,10);

will make . scan as one of the letters and thus make accessible all the compiler procedures.

CONSTRUCT(ARG)

returns the structure ARG with all names replaced by their values. Example:

BREAKUP($\geq([(A B) C 53], \geq([(X Y) Z] R 53)))$
PRINT(CONSTRUCT($\geq([(A B) C 65]));$)

will print $[(X Y) Z] R 65]$

COMPILE(LST)

LST is a list containing a BALM procedure without the terminating semicolon. COMPILE returns compiled code for that statement.

COPY(ARG)

returns a copy of its argument.

DUMMY(ARG)

returns ARG.

ERROR(TYPE)

called automatically when errors occur. TYPE is set as follows.

1 - no more space

2 - invalid type or pointer found by garbage collector

3 - attempt to execute something which is not a procedure

4 - attempt to execute an undefined op code

5 - invalid argument to I/O instruction, i.e., not a string or integer.

6 - attempt to goto a nonlabel.

EQUAL(ARG1,ARG2)

returns TRUE if ARG1 is the same as (or a copy of) ARG2.

EXECUTE(INFILE,OUTFILE)

EXECUTE translates and executes BALM statements from the file INFILE until a STOP statement is reached. EXECUTE will then return NIL. Translator error messages are written on file OUTFILE.

EXPAND(LST)

returns the result of a macro expansion on list LST.

LST is assumed to be in the same form as the output from the precedence analyzer.

GENSYM()

returns a unique identifier each time called.

GETPROP(ID,P)

refer to listing of the compiler supplement Appendix F.

IFROMID(ID)

returns an integer which is the symbol table entry number of ID.

INFIX(OP,LPREC,RPREC,PROCNAM)

defines infix operator OP with left precedence LPREC and right precedence RPREC. PROCNAM is the name of the corresponding procedure.

LENGTH(ARG)

returns the length of a string in characters or the number of top level elements in a list or vector.

LFROMV(VECT)

returns a list of the elements of VECT.

LOOKUP(ARG,LST)

refer to listing of the BALM4 compiler, Appendix F.

Assumes that LST is a list whose members are lists of two elements. LOOKUP searches LST to see if ARG is the first top level element of a member. If it is not then NIL is returned. If it is then the second top level element of the member is returned.

LOOKUP(ID1, ID2)

If the property field of ID1 is a list it is assumed to be a list whose members are themselves lists with two top level members. LOOKUP examines each member of the list to see if ID2 is its first top level element. If so then the second top level element of the member is returned, otherwise NIL.

MACRO(NAM, PROCED)

defines NAM as a macro with associated procedure PROCED.

MAKPROPS(ID1, ID2)

The value of ID2 is assumed to be a list whose members are lists of two elements. The first element of each member must be an identifier. MAKPROPS examines each member of the list and sets the property field of the first element to a list of ID1 and the second element of the member. When the entire list has been searched the value of ID2 is set to ID1.

(Refer to procedure LOOKUP and also to the supplementary listing).

MAKALOCAL(COND)

If COND is TRUE the compiler will make all procedure arguments not preceded by a \$ into verylocal variables i.e. known only within that procedure. If COND is NIL all arguments will be local and will be known to all procedures called within the scope of the procedures. COND=NIL is the current default mode.

MAKVLOCAL(COND)

If COND is TRUE the compiler will make the variables listed in begin blocks and not preceded by \$ into very local variables, i.e. known only within that block. If COND is NIL all variables listed within begin end blocks will be compiled as local regardless of whether they are preceded by \$ or not. They will be accessible to all blocks executed within the scope of the defining block. COND = NIL is the current default mode.

MAPX(ARG, PROCED)

MAPX applies the procedure PROCED to each of the top level elements of ARG, returning a list or vector of the results. If ARG is a list, then a list is returned; if ARG is a vector, then a vector is returned. ARG must not be a string.

MEMBER(ARG1,ARG2)

if ARG1 is a top level element of ARG2 (a list or vector)
then TRUE is returned, otherwise NIL.

ORDINAL(ARG,LST)

returns I when ARG is the Ith top level member of LST.
NIL is returned otherwise. Note ARG must be on the list;
if LST contains a copy of ARG, NIL will be returned.

PROCTRACE(LST)

LST is assumed to be the result of a STKTRACE(I) operation.
PROCTRACE produces a formatted procedure trace on the output
file.

PTRACE(ID)

prints the value of the arguments of procedure ID each time
it is called and prints the value of each RETURN.

REMINFIX(OP)

removes the most recently added occurrence of OP from the
infix list.

REMMACRO(NAM)

removes the most recently added occurrence of NAM from the
MACROLIST. Note that when the user creates a macro using
MEANS, NAM must be PROCNAME and not OP as described in
procedures INFIX and UNARY.

REMUNARY(OP)

removes the most recently added occurrence of OP from the
unary list.

RESTAT(V)

V is the output of procedure SAVSTAT. The states of OPLIST
MACROLIST, INFIXLIST, UNARYLIST and CODGENLIST are restored
to the same state as when SAVSTAT was executed.

SAVEBALM(S)

opens a file named S, rewinds the file, performs a garbage
collection, executes a SAVEALL on the file and closes the file.

SAVSTAT()

output is a vector which can be used as input to RESTAT to restore the state of the compiler.

SETPROP(NAME,PROP,VAL)

gives the property PROP with value VAL to the name NAME.

The previous value of this property (if present) is pushed down, and not lost. The name is returned.

SUBST(NEW,OLD,LST)

returns the list LST with all occurrences of OLD replaced by NEW. For example

```
X=SUBST(>(X Y),>(A(B C)),>(X Y ((A (B C)) Z));  
PRINT(X);
```

will print

```
(X Y ((X Y)) Z)
```

TRANSLATE(LST)

LST is a list containing a BALM statement without the terminating semicolon. TRANSLATE will return the statement translated into BALM internal form, suitable for compilation.

UNARY(OP,PREC,PROCNAM)

defines OP as a unary operator with precedence PREC and associated procedure name PROCNAM.

VFROML(LST)

returns a vector containing elements of list LST.

APPENDIX F

The following is in two parts. The first is a listing of the BALM4 compiler preceded by a bootstrap program which enables the compiler to produce a punched object deck. The second is additional BALM4 programs which are used to create a saved file of the BALM4 system.

```
